## **Safety instructions**

#### **UNCONTROLLED MACHINE ACTIONS**

To avoid uncontrolled machine actions caused by data loss, configure all the data transmission devices individually.

Before you start any machine which is controlled via data transmission, be sure to complete the configuration of all data transmission devices.

Failure to follow these instructions can result in death, serious injury, or equipment damage.

## **About this Manual**

The "GUI" reference manual contains detailed information on using the graphical interface to operate the individual functions of the device.

The "Command Line Interface" reference manual contains detailed information on using the Command Line Interface to operate the individual functions of the device.

The "Installation" user manual contains a device description, safety instructions, a description of the display, and the other information that you need to install the device.

The "Basic Configuration" user manual contains the information you need to start operating the device. It takes you step by step from the first startup operation through to the basic settings for operation in your environment.

The "Redundancy Configuration" user manual document contains the information you require to select the suitable redundancy procedure and configure it.

The "Routing Configuration User Manual" document contains the information you need to start operating the routing function. It takes you step-by-step from a small router application through to the router configuration of a complex network.

The manual enables you to configure your router by following the examples.

The document "HiView User Manual" contains information about the GUI application HiView. This application offers you the possibility to use the graphical user interface without other applications such as a Web browser or an installed Java Runtime Environment (JRE).

The Industrial HiVision network management software provides you with additional options for smooth configuration and monitoring:

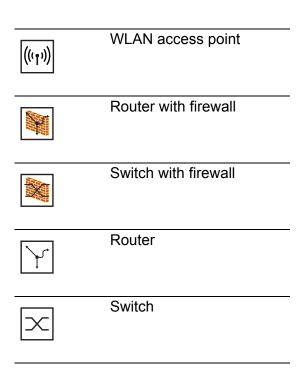

- ActiveX control for SCADA integration
- Auto-topology discovery
- Browser interface
- Client/server structure
- Event handling
- Event log
- ► Simultaneous configuration of multiple devices
- ► Graphical user interface with network layout
- ► SNMP/OPC gateway

# Key

# 1 Network Topology vs. Redundancy Protocols

When using Ethernet, an important prerequisite is that data packets follow a single (unique) path from the sender to the receiver. The following network topologies support this prerequisite:

- Line topology
- Star topology
- Tree topology

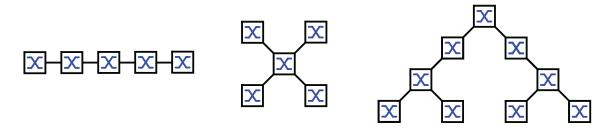

Figure 1: Network with line, star and tree topologies

To ensure that the communication is maintained when a connection fails, you install additional physical connections between the network nodes. Redundancy protocols ensure that the additional connections remain switched off while the original connection is still working. If the connection fails, the redundancy protocol generates a new path from the sender to the receiver via the alternative connection.

To introduce redundancy onto layer 2 of a network, you first define which network topology you require. Depending on the network topology selected, you then choose from the redundancy protocols that can be used with this network topology.

## 1.1 Network topologies

#### 1.1.1 Meshed topology

For networks with star or tree topologies, redundancy procedures are only possible in connection with physical loop creation. The result is a meshed topology.

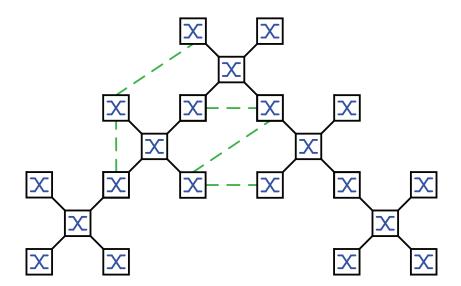

Figure 2: Meshed topology: Tree topology with physical loops

For operating in this network topology, the device provides you with the following redundancy protocols:

► Rapid Spanning Tree (RSTP)

#### 1.1.2 Ring topology

In networks with a line topology, you can use redundancy procedures by connecting the ends of the line. This creates a ring topology.

Figure 3: Ring topology: Line topology with connected ends

For operating in this network topology, the device provides you with the following redundancy protocols:

- ► Media Redundancy Protocol (MRP)
- ► High-availability Seamless Redundancy (HSR)
- Rapid Spanning Tree (RSTP)

## **1.2 Redundancy Protocols**

For operating in different network topologies, the device provides you with the following redundancy protocols:

Redundancy protocol	Network topology	Comments
HSR	Ring	Uninterrupted availability. On the path from the sender to the receiver, HSR transports the data packets in both directions via a ring.
MRP	Ring	The switching time can be selected and is practically independent of the number of devices.  An MRP-Ring consits of up to 50 devices that support the MRP protocol according to IEC 62439.  If you only use Hirschmann devices, up to 100 devices are possible in the MRP-Ring.
Subring	Ring	The subring function enables you to easily couple network segments to existing redundancy rings.
PRP	Random structure of the PRP LANs	Uninterrupted availability. On the path from the sender to the receiver, PRP transports a data packet in parallel via 2 mutually independent LANs.
RSTP	Random structure	The switching time depends on the network topology and the number of devices.  ▶ typ. < 1 s with RSTP  ▶ typ. < 30 s with STP
Link Aggrega- tion	Random structure	A Link Aggregation Group is the combining of 2 or more, full-duplex point-to-point links operating at the same rate, on a single switch to increase bandwidth.

Table 1: Overview of redundancy protocols

**Note:** When you are using a redundancy function, you deactivate the flow control on the participating device ports. If the flow control and the redundancy function are active at the same time, there is a risk that the redundancy function will not operate as intended.

# 2 Media Redundancy Protocol (MRP)

Since May 2008, the Media Redundancy Protocol (MRP) has been a standardized solution for ring redundancy in the industrial environment.

MRP is compatible with redundant ring coupling, supports VLANs, and is distinguished by very short reconfiguration times.

An MRP-Ring consists of up to 50 devices that support the MRP protocol according to IEC 62439. If you only use Hirschmann devices, up to 100 devices are possible in the MRP-Ring.

## 2.1 Network Structure

The concept of ring redundancy allows the construction of high-availability, ring-shaped network structures.

With the help of the RM (**R**ing **M**anager) function, the two ends of a backbone in a line structure can be closed to a redundant ring. The ring manager keeps the redundant line open as long as the line structure is intact. If a segment becomes inoperable, the ring manager immediately closes the redundant line, and line structure is intact again.

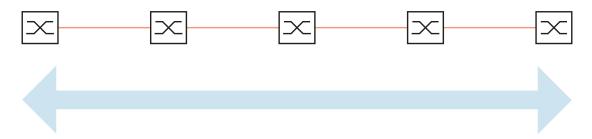

Figure 4: Line structure

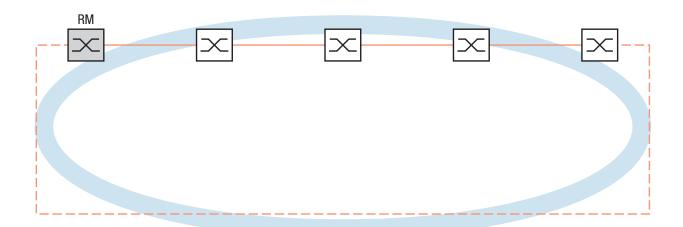

Figure 5: Redundant ring structure RM = Ring Manager —— main line - - - redundant line

## 2.2 Reconfiguration time

If a line section fails, the ring manager changes the MRP-Ring back into a line structure. You define the maximum time for the reconfiguration of the line in the ring manager.

Possible values for the maximum delay time:

- 500 ms
- 200 ms
- 30 ms
- 10 ms

The delay times 30ms and 10ms are only available to you for devices with hardware for enhanced redundancy functions.

In order to use these fast delay times, load the Fast MRP device software.

Configure the delay time to 10ms, when you use up to 20 devices in the ring, that support this delay time. When you use more than 20 of these devices in the ring, configure a delay time to at least 30ms.

**Note:** You only configure the reconfiguration time with a value less than 500 ms if all the devices in the ring support the shorter delay time. Otherwise the devices that only support longer delay times might not be reachable due to overloading. Loops can occur as a result.

## 2.3 Advanced mode

For times even shorter than the guaranteed reconfiguration times, the device provides the advanced mode. The advanced mode speeds up the link failure recognition when the ring participants inform the ring manager of interruptions in the ring via link-down notifications.

Hirschmann devices support link-down notifications. Therefore, you generally activate the advanced mode in the ring manager.

If you are using devices that do not support link-down notifications, the ring manager reconfigures the line in the selected maximum reconfiguration time.

## 2.4 Prerequisites for MRP

Before setting up an MRP-Ring, make sure that the following conditions are fulfilled:

All ring participants support MRP.

VLAN > Port dialog.

- ► The ring participants are connected to each other via the ring ports. Apart from the device's neighbors, no other ring participants are connected to the respective device.
- All ring participants support the configuration time defined in the ring manager.
- There is exactly 1 ring manager in the ring.

If you are using VLANs, configure every ring port with the following se	ttings:
☐ Deactivate ingress filtering - see the Switching:VLAN:Port Switching	ng >

- ☐ Define the port VLAN ID (PVID) see the Switching > VLAN > Port dialog.
  - PVID = 1 if the device transmits the MRP data packets untagged (VLAN ID = 0 in Switching > L2-Redundancy > MRP dialog)
     By setting the PVID = 1, the device automatically assigns the received untagged packets to VLAN 1.
  - PVID = any if the device transmits the MRP data packets in a VLAN (VLAN ID ≥ 1 in the Switching > L2-Redundancy > MRP dialog)
- $\square$  Define egress rules see Switching > VLAN > Configuration dialog.
  - U (untagged) for the ring ports of VLAN 1 if the device transmits the MRP data packets untagged (VLAN ID = 0 in the Switching > L2-Redundancy > MRP dialog, the MRP ring is not assigned to a VLAN).
  - T (tagged) for the ring ports of the VLAN which you assign to the MRP ring. Select T, if the device transmits the MRP data packets in a VLAN (VLAN ID ≥ 1 in the Switching > L2-Redundancy > MRP dialog).

You will find further information about setting the MRP VLAN ID in the figure "Changing the VLAN ID" on page 32.

## 2.5 Example Configuration

A backbone network contains 3 devices in a line structure. To increase the availability of the network, you convert the line structure to a redundant ring structure. Devices from different manufacturers are used. All devices support MRP. On every device you define ports 1.1 and 1.2 as ring ports.

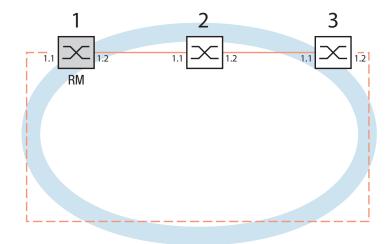

Figure 6: Example of MRP-Ring
RM = Ring Manager
—— main line
- - - redundant line

The following example configuration describes the configuration of the ring manager device (1). You configure the 2 other devices (2 to 3) in the same way, but without activating the ring manager function. This example does not use a VLAN. You have entered 200 ms as the ring recovery time, and all the devices support the advanced mode of the ring manager.

	Set up	the	network	to	meet	your	demands.
--	--------	-----	---------	----	------	------	----------

☐ Configure all ports so that the transmission speed and the duplex settings of the lines correspond to the following table:

Port type	Bit rate	Autonegotiation (automatic configuration)	Port setting	Duplex
TX	100 Mbit/s	off	on	100 Mbit/s full duplex (FDX)
TX	1 Gbit/s	on	on	-
Optical	100 Mbit/s	off	on	100 Mbit/s full duplex (FDX)
Optical	1 Gbit/s	on	on	-

Table 2: Port settings for ring ports

**Note:** You configure optical ports without support for autonegotiation (automatic configuration) with 100 Mbit/s full duplex (FDX) or 1000 Mbit/s full duplex (FDX).

**Note:** Configure all the devices of the MRP-Ring individually. Before you connect the redundant line, you must have completed the configuration of all the devices of the MRP-Ring. You thus avoid loops during the configuration phase.

- ☐ You deactivate the flow control on the participating ports.

  If the flow control and the redundancy function are active at the same time, there is a risk that the redundancy function will not operate as intended. (Default setting: flow control deactivated globally and activated on all ports.)
- ☐ Switch Spanning Tree off on all devices in the network:
  - ☐ Open the Switching > L2-Redundancy > Spanning Tree > Global dialog.
  - ☐ Switch off the function.
     In the state on delivery, Spanning Tree is switched on on the device.

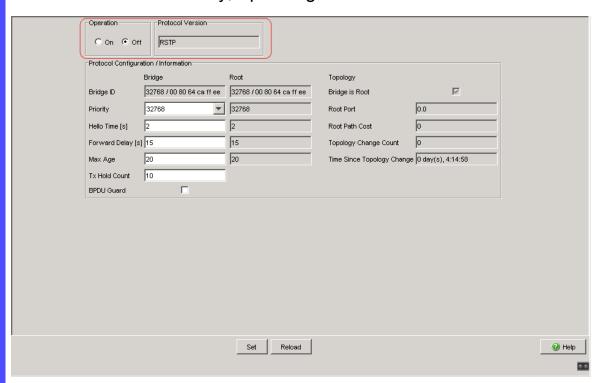

Figure 7: Switching the function off

enable
configure
no spanning-tree operation
show spanning-tree global

Switch to the privileged EXEC mode. Switch to the Configuration mode. Switches Spanning Tree off. Displays the parameters for checking.

- ☐ Switch MRP on on all devices in the network:
  - ☐ Open the Switching > L2-Redundancy > MRP dialog.
  - ☐ Define the desired ring ports.

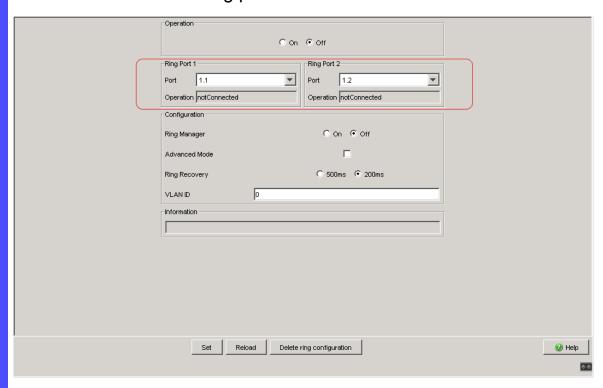

Figure 8: Defining the ring ports

In the Command Line Interface you first define an additional parameter, the MRP domain ID. Configure all the ring participants with the same MRP domain ID. The MRP domain ID is a sequence of 16 number blocks (8-bit values).

mrp domain add default-domain

Creates a new MRP domain with the default domain ID.

mrp domain modify port
 primary 1/1

mrp domain modify port
 secondary 1/2

Creates a new MRP domain with the default domain ID.

Defines port 1.1 as ring port 1 (primary).

Defines port 1.2 as ring port 2 (secondary).

☐ Activate the ring manager.

For the other devices in the ring, leave the setting as Off.

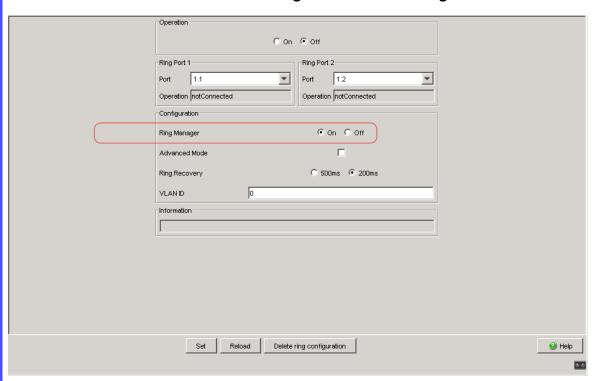

Figure 9: Activating the ring manager

mrp domain modify mode
 manager

Defines the device as the ring manager. Do not activate the ring manager on any other device.

Port 1.1 1.2 T • Port Operation notConnected Operation notConnected Configuration ● On ○ Off Ring Manager Advanced Mode C 500ms © 200ms Ring Recovery 0 VLAN ID Set Reload Delete ring configuration Help

☐ Select the checkbox in the "Advanced Mode" field.

Figure 10: Activating the advanced mode

mrp domain modify
 advanced-mode enabled

Activates the advanced mode.

☐ In the "Ring Recovery" field, select the value 200ms. Operation Port 1.1 1.2 ▼ Port Operation notConnected Operation notConnected Configuration ⊙ On ○ Off Ring Manager ┍ Advanced Mode Ring Recovery VLAN ID Set Reload Delete ring configuration Help

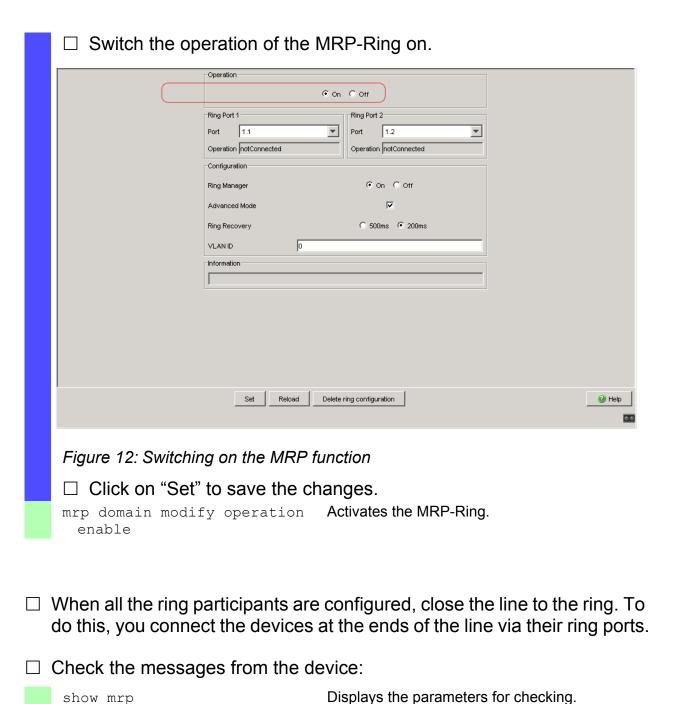

Figure 11: Defining the time for the ring recovery

mrp domain modify recovery-delay 200ms

Defines 200ms as the max. delay time for the reconfiguration of the ring.

**Note:** If selecting 200 ms for the ring recovery does not provide the ring stability necessary to meet the requirements of your network, you select 500 ms.

You will find further information about setting the MRP VLAN ID in the figure "Changing the VLAN ID" on page 32.

The "Operation" field shows the operating state of the ring port.

#### Possible values:

- forwarding
  - Port is switched on, connection exists.
- blocked
  - Port is blocked, connection exists.
- disabled
  - Port is disabled.
- not connected
  - No connection exists.

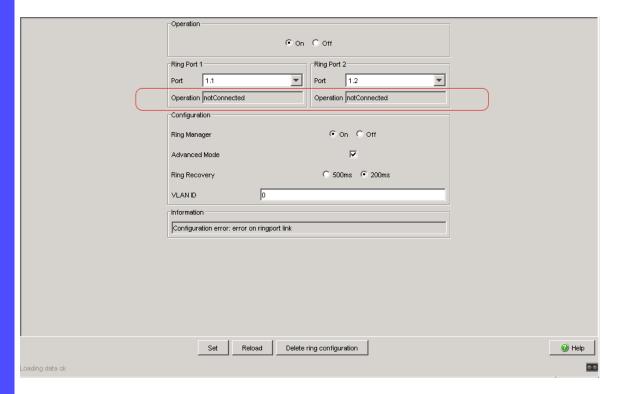

Figure 13: Messages in the "Operation" field

The "Information" field shows messages for the redundancy configuration and the possible causes of errors.

The following messages are possible if the device is operating as a ring client or a ring manager:

- ▶ Redundancy Available The redundancy is set up. When a component of the ring is down, the redundant line takes over its function.
- Configuration error: Ring port link error Error in the cabling of the ring ports.

The following messages are possible if the device is operating as a ring manager:

Configuration error:Packet of other ring manager received

Another device exists in the ring that is operating as the ring manager.

Activate the "Ring Manager" function on exactly one device in the ring.

Configuration error: Connection in ring is connected to incorrect port

A line in the ring is connected with a different port instead of with a ring port. The device only receives test data packets on 1 ring port.

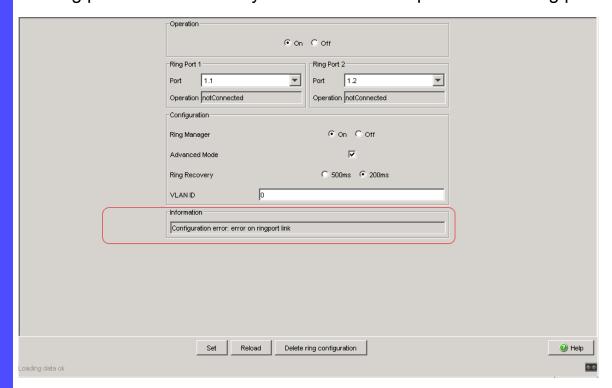

Figure 14: Messages in the "Information" field

- ☐ If applicable, integrate the MRP ring into a VLAN:
  - ☐ In the "VLAN ID" field, define the MRP VLAN ID. The MRP VLAN ID determines in which of the configured VLANs the device transmits the MRP packets. To set the MRP VLAN ID, first configure the VLANs and the corresponding egress rules in the Switching > VLAN > Configuration dialog.

See "Prerequisites for MRP" on page 21.

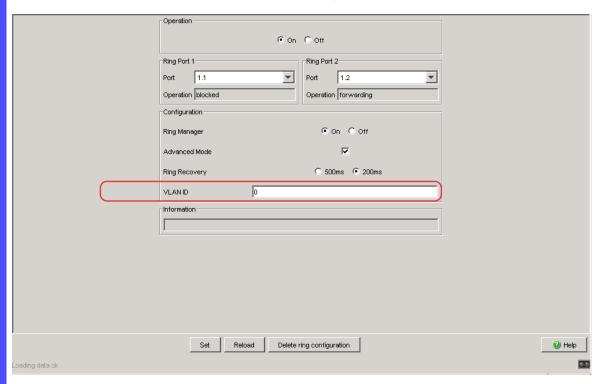

Figure 15: Changing the VLAN ID

- ▶ If the MRP-Ring is not assigned to a VLAN (like in this example), leave the VLAN ID as 0.
  - In the Switching > VLAN > Configuration dialog, define the VLAN membership as U (untagged) for the ring ports in VLAN 1.
- ▶ If the MRP-Ring is assigned to a VLAN, enter a VLAN ID >0.
  In the Switching > VLAN > Configuration dialog, define the VLAN membership as T (tagged) for the ring ports in the selected VLAN.

# 3 Mulitple Rings (HiOS-2A, HiOS-3S)

The device allows you to set up multiple rings with different redundancy protocols:

- ▶ You have the option of nesting MRP rings. A coupled ring is a subring.
- You have the option of coupling other ring structures that work with RSTP to MRP rings.

#### 3.1 **Subring (HiOS-2A, HiOS-3S)**

The Subring function is an extension of the Media Redundancy Protocol (MRP). This function allows you to couple a subring to a main ring using various network structures.

The Subring protocol provides redundancy for devices by coupling both ends of an otherwise flat network to a main ring.

Setting up subrings has the following advantages:

- Through the coupling process, you include the new network segment in the redundancy concept.
- Subrings allow easy integration of new areas into existing networks.
- Subrings allow you easy mapping of the organizational structure of an area in a network topology.
- In an MRP ring, the failover times of the subring in redundancy cases are typically < 100 ms.

#### 3.1.1 Subring description

The subring concept allows you to couple new network segments to suitable devices in an existing ring (main ring). The devices with which you couple the subring to the main ring are Subring Managers (SRM).

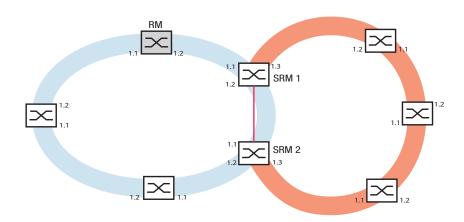

Figure 16: Example of a subring structure
blue ring = Main ring
orange ring = Subring
red line = Redundant link
SRM = Subring Manager
RM = Ring Manager

The Subring Manager capable devices support up to 8 instances and thus manage up to 8 subrings at the same time.

The Subring function allows you to integrate devices that support MRP as participants. The devices with which you couple the subring to the main ring require the Subring Manager function.

Each subring can consist of up to 200 participants, excluding the Subring Managers themselves and the devices between the Subring Managers in the main ring.

The following figures show examples of possible subring topologies:

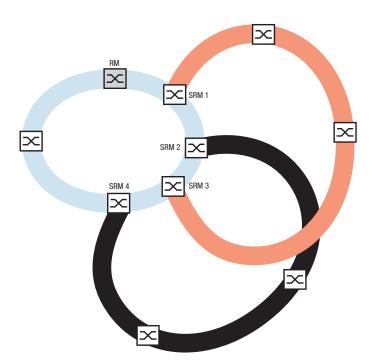

Figure 17: Example of an overlapping subring structure

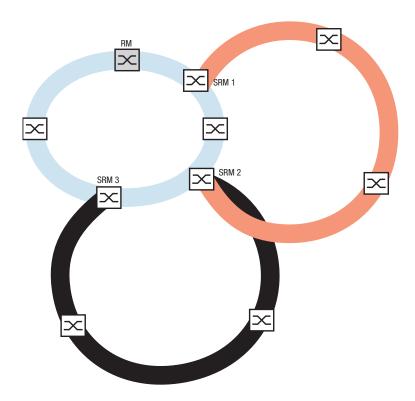

Figure 18: Special case: a Subring Manager manages 2 subrings (2 instances).

The Subring Manager is capable of managing up to 8 instances.

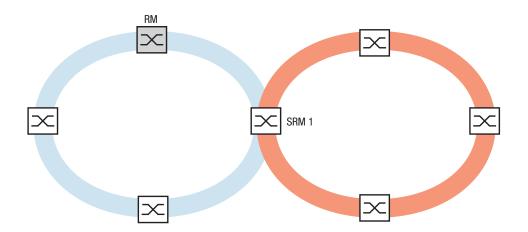

Figure 19: Special case: a Subring Manager manages both ends of a subring on different ports (Single Subring Manger).

**Note:** In the previous examples, the Subring Managers couple subrings solely to existing main rings. The Subring function prohibits cascaded subrings, for example coupling a new subring to another existing subring.

When you use MRP for the main ring and the subring, then specify the VLAN settings as follows:

- VLAN x for main ring
  - on the ring ports of the main ring participants
  - on the main ring ports of the subring manager
- ► VLAN Y for subring
  - on the ring ports of the subring participants
  - on the subring ports of the subring manager You can use the same VLAN for multiple subrings

### 3.1.2 Subring example

In the following example, you couple a new network segment with 3 devices to an existing main ring which uses the MRP protocol. If you couple the network at both ends instead of just 1 end, then the subring provides increased availability with the corresponding configuration.

You couple the new network segment as a subring. You couple the subring to the existing devices of the main ring using the following configuration types.

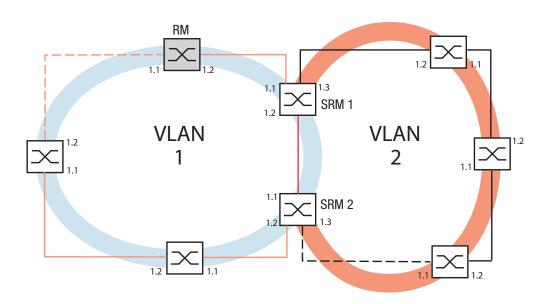

Figure 20: Example of a subring structure
orange line= Main ring members in VLAN 1
black line= Subring members in VLAN 2
orange dash line= Main ring loop open
black dash line= Subring loop open
red line = Redundant link member in VLAN 1
SRM = Subring Manager
RM = Ring Manager

Proceed as follows to configure a subring:

- ☐ Configure the three devices of the new network segment as participants in an MRP ring:
  - Configure the transmission rate and the duplex mode for the ring ports in accordance with the following table:

Port type	Bit rate	Autonegotiation (automatic configuration)	Port setting	Duplex
TX	100 Mbit/s	off	on	100 Mbit/s full duplex (FDX)
TX	1 Gbit/s	on	on	-
Optical	100 Mbit/s	off	on	100 Mbit/s full duplex (FDX)
Optical	1 Gbit/s	on	on	-
Optical	10 Gbit/s	-	on	10 Gbit/s full duplex (FDX)

Table 3: Port settings for subring ports

The following steps contain additional settings for subring configuration: ☐ To help prevent loops during configuration, deactivate the Subring Manager function on the main ring and subring devices. After you completely configure every device participating in the main ring and subrings activate the global Subring function and Subring Managers. ☐ Disable the RSTP function on the MRP ring ports used in the subring. ☐ Verify that the Link Aggregation function is inactive on ports participating in the main ring and subring.

- ☐ Specify a different VLAN membership for the main ring ports and subring ports even if the main ring is using the MRP protocol. For example, use VLAN ID 1 for the main ring and the redundant link, then use VLAN ID 2 for the subring.
  - For the devices participating in the main ring for example, open the Switching > VLAN > VLAN Configuration dialog. Create VLAN 1 in the static VLAN table. Tag the main ring ports for membership in VLAN 1 by selecting T from the dropdown list of the appropriate port fields.
  - For the devices participating in the subring use the step above and assign the ports to VLAN 2 in the static VLAN table.
- ☐ Activate the MRP ring function for the main ring and subring devices.
  - In the Switching > L2-Redundancy > MRP dialog, configure the 2 ring ports participating in the main ring on the main ring devices.
  - For the devices participating in the subring use the step above and configure the 2 ring ports participating in the subring on the subring devices.
  - Assign the same MRP domain ID to the main ring and subring devices. If you use Hirschmann Automation and Control GmbH devices solely, then the default values suffice for the MRP domain ID.

Note: The "MRP Domain" is a sequence of 16 numbers in the range from 0 to 255. The default value is 255 . 255 . 255 . 255 . 255 . 255 . 255 . 255 . 255 . 255 . 255 . 255 . 255 . 255 . 255 . A "MRP Domain" consisting entirely of zeroes is invalid.

The "Sub Ring" dialog allows you to change the MRP domian ID if required, or open the Command Line Interface (CLI) and proceed as follows:

enable configure mrp domain delete mrp domain add domain-id 0.0.1.1.2.2.3.4.4.111. 222.123.0.0.66.99

Switch to the privileged EXEC mode. Switch to the Configuration mode. Deletes the current MRP domain. Creates a new MRP domain with the specified MRP domain ID. Any subsequent MRP domain changes apply to this domain ID.

#### 3.1.3 Subring example configuration

**Note:** Avoid loops during configuration. Configure every device of the subring individually. Before you activate the redundant link, completely configure every subring device.

Proceed as follows to configure the 2 Subring Managers in the example:

 $\square$  Open the Switching > L2-Redundancy > Sub Ring dialog. ☐ To open the "New Entry" dialog, click "Create". Sub Ring ID 2 All SRM Mode manager 2 MRP Domain 255.255.255.255.255.255.25 Set Set and back Back Help

Figure 21: New Entry dialog

- ☐ The device displays the value for the next available "Sub Ring ID".
- ☐ Use the dropdown list in the "Port" field to select the port that couples the device to the subring. Use port 1/3 for this example. The dropdown list displays every device port. For coupling, use the ports available with the exception of the ports which are already connected to the main ring.

- ☐ Enter a name for the subring. For this example enter Test.
- ☐ Select the appropriate Subring Manager mode from the "SRM Mode" dropdown list.

You thus specify which port coupling the subring to the main ring becomes the redundant manager.

The options for the coupling are:

manager

When you specify both Subring Managers as the same value, the device with the higher MAC address manages the redundant link.

redundant manager

This device manages the redundant link, as long as you have specified the other Subring Manager as a manager. Otherwise the device with the higher MAC address manages the redundant link.

Specify Subring Manager 1 as manager, in accordance with the figure depicting this example.

- □ Leave the "VLAN" field and the "MRP Domain" field as set by default. These values are correct for the example configuration.
- ☐ To temporarily save the changes and return to the "Sub Ring" dialog, click "Set and back".
- ☐ To update the table in the "Sub Ring" dialog and verify the entries, click "Reload".

# 4 Parallel Redundancy Protocol (PRP)

Unlike ring redundancy protocols, PRP uses 2 separate LANs for uninterrupted availability. On the path from the sender to the receiver, PRP sends 2 data packets in parallel via the 2 mutually independent LANs. The receiver processes the first data packet received and discards the second data packet of the pair. The international standard IEC 62439-3 defines the Parallel Redundancy Protocol (PRP).

Note: If PRP is active, it uses the interfaces 1/1 and 1/2. As seen in the Switching > VLAN, Switching > Rate Limiter and Switching > Filter for MAC Addresses dialogs, the PRP function replaces the interfaces 1/1 and 1/2 with the interface prp/1. Configure the VLAN membership, the rate limiting, and the MAC filtering for the interface prp/1.

# 4.1 Implementation

When the upper protocol layers send a data packet, the PRP interface creates a "twin packet" from the original packet. The PRP interface then transmits 1 data packet of the pair to each participating LAN simultaneously. The packets traverse different LANs and therefore have different run times.

The receiving PRP interface forwards the first packet of a pair towards the upper protocol layers and discards the second packet. When viewed from the application, a PRP interface functions like a standard Ethernet interface.

The PRP interface or a Redundancy Box (RedBox) injects a Redundancy Control Trailer (RCT) into each packet. The RCT is a 48-bit identification field and is responsible for the identification of duplicates. This field contains, LAN identification (LAN A or B), information about the length of the payload, and a 16-bit sequence number. The PRP interface increments the sequence number for each packet sent. Using the unique attributes included in each packet, such as Physical MAC source address and sequence number, the receiving RedBox or Double Attached Node (DAN) interface identifies and discards duplicates.

Depending on the packet size, with PRP it attains a reduced throughput of the available bandwidth, due to the addition of the RCT trailer.

# 4.2 LRE Functionality

Each Double Attached Node implementing PRP (DANP) has 2 LAN ports that operate in parallel. The Link Redundancy Entity (LRE) connects the upper protocol layers with every individual port.

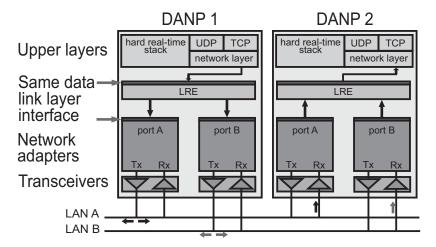

Figure 23: PRP LRE process

The LRE has the following tasks:

- Handling of duplicates
- Management of redundancy

When transmitting packets from the upper protocol layers, the LRE sends them from both ports at nearly the same time. The 2 data packets pass through the LANs with different delays. When the device receives the first data packet, the LRE forwards it to the upper protocol layers and discards the second data packet received.

For the upper protocol layers, the LRE behaves like a normal port.

To identify the twin packets, the LRE attaches an RCT with a sequential number to the packets. The LRE also periodically sends multicast PRP supervision packets and evaluates the multicast PRP supervision packets of the other RedBoxes and DANPs.

The device allows you to view the received supervision packet entries. The entries in the <code>Switching > L2-Redundancy > PRP > DAN/VDAN Table</code> are helpful for detecting redundancy and connection problems. For example, in an index when the "Last Seen B" timestamp resets and the "Last Seen A" timestamp remains the same. The "Last Seen A" and "Last Seen B" timestamps steadily reseting indicate a normal condition.

**Note:** According to IEC 62439 the Entry Forget Time is 400 ms. The Entry Forget Time is the time after which the device removes an entry from the duplicate table. When the device receives the second frame of a pair after 400 ms, then the device processes the frame instead of discarding it. For this reason, Hirschmann recommends that the number of nodes installed in your PRP network remain under 10 nodes.

**Note:** If the inter-frame gap is shorter than the latency between the 2 LANs, a frame-ordering mismatch can occur. Frame-ordering mismatch is a phenomenon of the PRP protocol. The only solution for avoiding a frame-ordering mismatch is to verify that the inter-frame gap is greater than the latency between the LANs.

### 4.3 PRP Network Structure

PRP uses 2 independent LANs. The topology of each of these LANs is arbitrary, and ring, star, bus and meshed topologies are possible.

The main advantage of PRP is zero recovery time with an active (transit) LAN. When the terminal device receives no packets from one of the LANs, the second (transit) LAN maintains the connection. As long as 1 (transit) LAN is available, repairs and maintenance on the other (transit) LAN have no impact on the data packet transmission.

The elementary devices of a PRP network are the RedBox (Redundancy Box) and the DANP (Double Attached Node implementing PRP). Both devices have 1 connection each to the (transit) LANs.

The devices in the (transit) LAN are conventional switches. The devices transmit PRP data packets transparently, without evaluating the RCT information.

**Note:** The RCT trailer increases packet size. Configure the MTU size equal to or greater than 1524 for LAN A and LAN B devices.

Terminal devices that connect directly to a device in the (transit) LAN are SANs (Single Attached Nodes). SANs connected to a LAN have no redundancy. To use the PRP redundant network, connect the SAN to the PRP network via a RedBox.

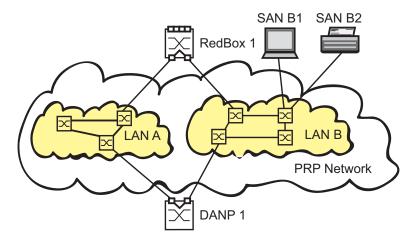

Figure 24: Parallel Redundancy Protocol Network

# 4.4 Connecting RedBoxes and DANPs to a PRP network

DANPs have 2 interfaces for the connection to the PRP network. A RedBox is a DANP that contains additional switch ports. Use the switch ports to intagrate one or more SANs into the PRP network redundantly.

The Link Redundancy Entity (LRE) in the RedBox creates a twin packet when sending a data packet to the PRP network. The LRE forwards 1 data packet of the twin pair when it receives it and discards the 2nd data packet of the twin pair.

**Note:** The Redbox supports up to 128 hosts. When attempt to support more than 128 with the Redbox, then device drops packets.

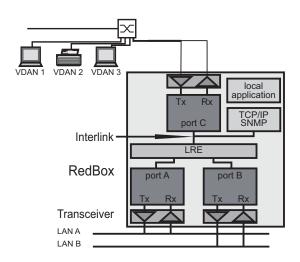

Figure 25: RedBox Transition from double to single LAN

# 4.5 Example Configuration

The following example uses a simple PRP network with 4 devices. Verify that the LAN A and LAN B ports contain 100 Mbit/s optical SFP interfaces. Connect Port A to LAN A and the Port B to LAN B.

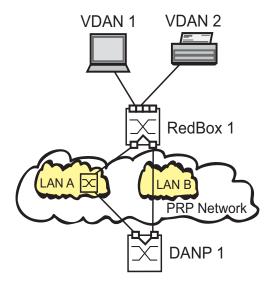

Figure 26: Example PRP Network

**Note:** PRP is available for devices with hardware for enhanced redundancy functions. In order to use the PRP functions, load the PRP device software.

The PRP function reserves ports 1/1 and 1/2. This removes the possibility of using other redundancy protocols such as Spanning Tree or MRP in parallel on ports 1/1 and 1/2.

- If you use Spanning Tree in parallel to PRP, deactivate Spanning Tree on ports 1/1 and 1/2. Also deactivate the functions "Root Guard", "TCN Guard" and "Loop Guard" on ports 1/1 and 1/2.
- ☐ If you use MRP in parallel to PRP, specify the other free device ports as MRP-Ring ports.

Per	form the following steps on both the RedBox 1 and DANP 1 devices.
	☐ Open the Switching > L2-Redundancy > PRP > Configuration dialog.
	Perform the following step in the "Supervision Packet Receiver" frame:  To analyze received PRP supervision packets, activate the "Evaluate Supervision Packets" checkbox.
	Perform the following steps in the "Supervision Packet Transmitter"
	frame:
	□ To transmit PRP supervision packets from this device, activate "Active".
	☐ The device sends either its own PRP supervision packets exclusively, or sends both its own supervision packets and packets of connected devices. To transmit packets for VDANs listed in the
	Switching > L2-Redundancy > PRP > DAN/VDAN Table, activate "Send VDAN Packets". When deactivated the device sends its own supervision packets exclusively. After installing new PRP devices,
	deactivate this function to maintain a clear overview of the PRP supervision packets on remote devices.
	☐ To enable the ports, in the "Port A" and "Port B" frames, click on.
	☐ To enable the PRP function, in the "Operation" frame click on.
	☐ To temporarily save the changes, click "Set".
	☐ To load the configuration saved in the volatile memory, click "Reload".
	☐ Open the Switching > L2-Redundancy > PRP > Proxy Node Table dialog to view the terminating VDAN devices for which this device provides PRP conversion.
	☐ To remove this list, click "Reset".
	☐ To load the list of currently connected devices, click "Reload".
	Open the Switching > L2-Redundancy > PRP > Statistics dialog to view the quality of the traffic that traverses the device. The device detects errors and displays them according to MIB Managed Objects
	and the respective link.
	☐ To remove the entry in the statistics table, click "Reset".
	☐ To load the current statistics, click "Reload".

### 4.6 PRP and Port Mirroring

The transceivers send traffic to the LRE, which separates the traffic. The LRE forwards the data frames to PRP Port A and the control frames to PRP Port B of the switch.

When you configure the PRP Port A as a source port, the device sends the control frames to the destination port. When you configure the PRP Port B as a source port, the device sends the data frames to the destination port. Configure Port A and Port B in the Switching > L2-Redundancy > PRP > Configuration dialog.

The device also restricts the PRP interface and the PRP member ports from being destination ports.

# 5 High-availability Seamless Redundancy (HSR)

As with PRP, an HSR ring also offers zero recovery time. HSR is suited for applications that demand high availability and short reaction times. For example, protection applications for electrical station automation and controllers for synchronized drives which require constant connection.

**Note:** If HSR is active, it uses the interfaces 1/1 and 1/2. As seen in the Switching > Rate Limiter and Switching > Filter for MAC Addresses dialogs, the HSR function replaces the interfaces 1/1 and 1/2 with the interface hsr/1. Set up the VLAN membership and the rate limiting for the interface hsr/1.

# 5.1 Implementation

HSR Redundancy Boxes (RedBox) use 2 Ethernet ports operating in parallel to connect to a ring. An HSR RedBox operating in this configuration is a Doubly Attached Node implementing the HSR protocol (DANH). A standard ethernet device connected to the HSR ring through an HSR RedBox is a Virtual DANH (VDANH).

As with PRP, the transmitting HSR Node or HSR RedBox sends twin frames, 1 in each direction, on the ring. For identification, the HSR Node injects the twins with an HSR tag. The HSR tag consists of a port identifier, the length of the payload and a sequence number. In a normal operating ring, the destination HSR Node or RedBox receives both frames within a certain time skew. An HSR node forwards the first frame to arrive and discards the second frame when it arrives. An HSR RedBox on the other hand forwards the first frame to the VDANHs and discards the second frame when it arrives.

The HSR Nodes and HSR RedBoxs insert an HSR tag after the source MAC Address in the frame. The advantage to the HSR tag placement is that the device is able to forward the frame immediately after receiving the HSR header and performing duplicate recognition. Affectively decreasing the delay time within the device. In contrast to PRP where the RCT contains a PRP suffix near the end of the frame. Meaning that a PRP device receives the entire frame before forwarding the frame out of the correct port.

HSR Nodes and HSR RedBoxes also use the LRE function as described in the PRP chapter. As with PRP, the LRE in the HSR RedBoxes are responsible for tagging and duplicate recognition.

Limit the maximum number of nodes in an HSR ring to 10, so that a DAN or Redbox receives these packets within a specific time frame.

**Note:** HSR is available for devices with hardware for enhanced redundancy functions. In order to use the HSR functions, load the HSR device software.

### **5.2 HSR Network Structure**

An HSR Network consists of a ring, where each HSR device performs a specific role in the network. An HSR device for example, connects standard ethernet devices to an HSR ring, or PRP LANs to an HSR ring.

### 5.2.1 Connecting SANs to an HSR Network

Standard ethernet devices, such as maintenance laptops or printers, have 1 network interface. Therefore, standard ethernet devices transmit traffic across an HSR ring through an HSR RedBox which acts as a proxy for the ethernet devices attached to it. The HSR RedBox interfaces transmit 1 twin in each direction around the network.

The host HSR RedBox forwards the first unicast frame to the destination VDANH exclusively and discards the second unicast frame when it arrives.

The HSR Nodes and RedBoxes forward multicast and broadcast traffic around the ring and also to the connected VDANH devices. To help prevent the traffic from endlessly looping around the ring, the node originally transmitting the traffic on the network discards the transmitted frames when received.

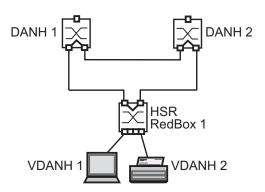

Figure 27: Connecting a VDANH to an HSR network

### ■ SAN Device Connection Example Configuration

A simple HSR network consists of 3 HSR devices as seen in the previous figure. The following example configures a host HSR RedBox for standard ethernet devices.

Deactivate STP on the PRP ports or globally. Also, deactivate MRP on the PRP ports or configure MRP on ports other than the PRP ports.

$\square$ Open the Switching > L2-Redundancy > MRP dialog.
☐ To disable the MRP function, in the Operation frame "Operation""Off".
Verify that the ports in "Ring Port 1" and "Ring Port 2" frames, are different from the ports used by HSR.
☐ <b>Open the</b> Switching > L2-Redundancy > Spanning Tree > Globa dialog.
To disable the MRP function, in the Operation frame "Operation" off".
☐ <b>Open the</b> Switching > L2-Redundancy > Spanning Tree > Port dialog.
☐ In the "CIST" tab, deactivate the ports used for HSR in the "Stp active" column.
☐ In the "Guards" tab, deactivate the ports used for HSR in the "Roo Guard" "TCN Guard" and "Loop Guard" columns

### 5.2.2 HSR and PRP network connections

When connecting PRP networks to an HSR network, the HSR device uses 2 interfaces to connect to the HSR ring. The HSR device uses a third interface to connect to either LAN A or LAN B of the PRP network as seen in the following figure. The HSR device transmitting the traffic across the HSR ring identifies traffic destine for PRP networks with the appropriate tag. The HSR devices then forward the PRP traffic through LAN A or LAN B. The PRP device receives the traffic and processes it as described in the PRP chapter.

The HSR devices tag and identify traffic for up to 7 PRP networks connected to 1 HSR ring.

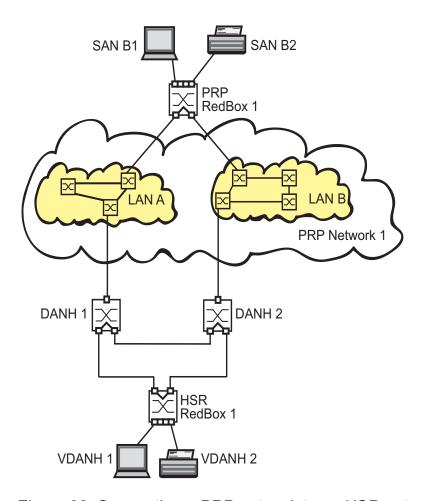

Figure 28: Connecting a PRP network to an HSR network

HSR Redboxes use 2 interfaces for the HSR ring. When configured to manage PRP traffic, a third interface connects to a LAN of the PRP network. The other interfaces provide HSR network access for VDANs. The HSR RedBox lists the connected VDANs in the <code>Switching > L2-Redundancy > HSR > Proxy Node Table</code>.

### PRP Network Connection Example Configuration

The following example configures a simple HSR network with 3 HSR devices as shown in the previous figure. Use the HSR RedBox configured in the previous example to connect the standard ethernet devices to the HSR ring. HSR RedBox 1 sends 1 twin toward DANH 1 and 1 twin toward DANH 2. When the first frame of a pair arrives, DANH 1 sends frame to PRP network 1 LAN A and DANH 2 sends the frame to PRP network 1 LAN B.

Deactivate STP on the PRP ports or globally. Also, deactivate MRP on the PRP ports or configure MRP on ports other than the PRP ports.

Use the HSR RedBox configured in the previous example for HSR RedBox 1. Perform the following steps on the DANH 1 and 2.

$\square$ <b>Open the</b> Switching > L2-Redundancy > MRP <b>dialog</b> .
To disable the MRP function, in the Operation frame "Opera-tion""Off".
<ul> <li>Verify that the ports in "Ring Port 1" and "Ring Port 2" frames, are different from the ports used by HSR.</li> </ul>
☐ <b>Open the</b> Switching > L2-Redundancy > Spanning Tree > Global dialog.
To disable the MRP function, in the Operation frame "Opera-tion""Off".
☐ <b>Open the</b> Switching > L2-Redundancy > Spanning Tree > Port dialog.
□ In the "CIST" tab, deactivate the ports used for HSR in the "Stp active" column.
☐ In the "Guards" tab, deactivate the ports used for HSR in the "Root Guard", "TCN Guard" and "Loop Guard" columns.
Note: If you deactivate the HSR function, then deactivate either Port "A"

or "B" to help prevent network loops.

The device sends either its own HSR supervision packets exclusively, or sends both its own supervision packets and packets of connected devices. After installing new HSR devices, deactivate this function to maintain a clear overview of the HSR supervision packets on remote devices.

☐ Open the Switching	>	L2-Redundancy	>	HSR	>	HSR	>	HSR	>
Configuration dialog.									

□ To analyze received HSR supervision packets, activate the "Evaluate Supervision Packets" checkbox in the "Supervision Packet Receiver" frame.
☐ To transmit HSR supervision packets from this device, activate "Active"in the "Supervision Packet Transmitter" frame.
☐ To transmit packets for VDANs listed in the Switching > L2-Redundancy > HSR > DAN/VDAN Table dialog, activate "Send VDAN Packets".
Use the following steps to configure DANH 1:
☐ Open the Switching > L2-Redundancy > HSR > HSR > HSR > Configuration dialog.
☐ To configure the device to forward unicast traffic around the ring and to the destination device, set the "HSR Mode" to modeu.
☐ To configure the device to forward traffic to PRP LAN A, set the "Switching Node Type" to hsrredboxprpa.
☐ To configure the device to forward traffic to PRP network 1 LAN A, set "Redbox Identity" to idla.
☐ To enable the ports, in the Port "Port A" and Port "Port B"frames, click "On".
<ul><li>□ To disable the HSR function, in the "Operation" frame, click "On".</li><li>□ To temporarily save the changes, click "Set".</li></ul>
☐ To load the configuration saved in the volatile memory, click "Reload".
Use the following configuration for DANH 2:
$\square$ Open the Switching > L2-Redundancy > HSR > HSR > HSR > Configuration dialog.
☐ To configure the device to forward unicast traffic around the ring and to the destination device, set the "HSR Mode" to modeu.
☐ To configure the device to forward traffic to PRP LAN A, set the "Switching Node Type" to hsrredboxprpb.
☐ To configure the device to forward traffic to PRP network 1 LAN B, set "Redbox Identity" to idlb.
□ To enable the ports, in the Port "Port A" and Port "Port B"frames, click "On".
$\hfill \square$ To disable the HSR function, in the "Operation"frame, click "On".
☐ To temporarily save the changes, click "Set".
To load the configuration saved in the volatile memory, click "Reload".

# Another possibility is to use the following CLI commands to configure the HSR devices 1 and 2.

# 6 Spanning Tree

**Note:** The Spanning Tree Protocol is a protocol for MAC bridges. For this reason, the following description uses the term bridge for Switch.

Local networks are getting bigger and bigger. This applies to both the geographical expansion and the number of network participants. Therefore, it is advantageous to use multiple bridges, for example:

- to reduce the network load in sub-areas,
- to set up redundant connections and
- to overcome distance limitations.

However, using multiple bridges with multiple redundant connections between the subnetworks can lead to loops and thus loss of communication across of the network. In order to help avoid this, you can use Spanning Tree. Spanning Tree enables loop-free switching through the systematic deactivation of redundant connections. Redundancy enables the systematic reactivation of individual connections as needed.

RSTP is a further development of the Spanning Tree Protocol (STP) and is compatible with it. If a connection or a bridge becomes inoperable, the STP required a maximum of 30 seconds to reconfigure. This is no longer acceptable in time-sensitive applications. RSTP achieves average reconfiguration times of less than a second. When you use RSTP in a ring topology with 10 to 20 devices, you can even achieve reconfiguration times in the order of milliseconds.

**Note:** RSTP reduces a layer 2 network topology with redundant paths into a tree structure (Spanning Tree) that does not contain any more redundant paths. One of the Switches takes over the role of the root bridge here. The maximum number of devices permitted in an active branch (from the root bridge to the tip of the branch) is specified by the variable Max Age for the current root bridge. The preset value for Max Age is 20, which can be increased up to 40.

If the device working as the root is inoperable and another device takes over its function, the Max Age setting of the new root bridge determines the maximum number of devices allowed in a branch.

**Note:** The RSTP standard dictates that all the devices within a network work with the (Rapid) Spanning Tree Algorithm. If STP and RSTP are used at the same time, the advantages of faster reconfiguration with RSTP are lost in the network segments that are operated in combination.

A device that only supports RSTP works together with MSTP devices by not assigning an MST region to itself, but rather the CST (Common Spanning Tree).

### 6.1 Basics

Because RSTP is a further development of the STP, all the following descriptions of the STP also apply to the RSTP.

### 6.1.1 The tasks of the STP

The Spanning Tree Algorithm reduces network topologies built with bridges and containing ring structures due to redundant links to a tree structure. In doing so, STP opens ring structures according to preset rules by deactivating redundant paths. If a path is interrupted because a network component becomes inoperable, STP reactivates the previously deactivated path again. This allows redundant links to increase the availability of communication. STP determines a bridge that represents the STP tree structure's base. This bridge is called root bridge.

### Features of the STP algorithm:

- automatic reconfiguration of the tree structure in the case of a bridge becoming inoperable or the interruption of a data path
- the tree structure is stabilized up to the maximum network size,
- stabilization of the topology within a short time period
- topology can be specified and reproduced by the administrator
- transparency for the terminal devices
- low network load relative to the available transmission capacity due to the tree structure created

### 6.1.2 Bridge parameters

In the context of Spanning Tree, each bridge and its connections are uniquely described by the following parameters:

- Bridge Identifier
- ► Root Path Cost for the bridge ports,
- Port Identifier

### 6.1.3 Bridge Identifier

The Bridge Identifier consists of 8 bytes. The 2 highest-value bytes are the priority. The default setting for the priority number is 32,768, but the Management Administrator can change this when configuring the network. The 6 lowest-value bytes of the bridge identifier are the bridge's MAC address. The MAC address allows each bridge to have unique bridge identifiers.

The bridge with the smallest number for the bridge identifier has the highest priority.

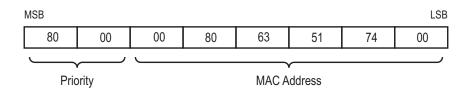

Figure 29: Bridge Identifier, Example (values in hexadecimal notation)

#### 6.1.4 Root Path Cost

Each path that connects 2 bridges is assigned a cost for the transmission (path cost). The Switch determines this value based on the transmission speed (see table 4). It assigns a higher path cost to paths with lower transmission speeds.

Alternatively, the Administrator can set the path cost. Like the Switch, the Administrator assigns a higher path cost to paths with lower transmission speeds. However, since the Administrator can choose this value freely, he has a tool with which he can give a certain path an advantage among redundant paths.

The root path cost is the sum of all individual costs of those paths that a data packet has to traverse from a connected bridge's port to the root bridge.

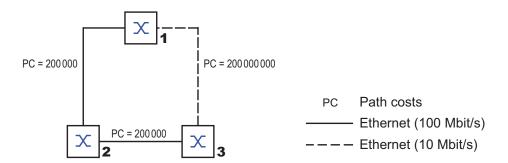

Figure 30: Path costs

Data rate	Recommended value	Recommended range	Possible range
≤100 Kbit/s	200,000,000 <sup>a</sup>	20,000,000-200,000,000	1-200,000,000
1 Mbit/s	20,000,000 <sup>a</sup>	2,000,000-200,000,000	1-200,000,000
10 Mbit/s	2,000,000 <sup>a</sup>	200,000-20,000,000	1-200,000,000
100 Mbit/s	200,000 <sup>a</sup>	20,000-2,000,000	1-200,000,000
1 Gbit/s	20,000	2,000-200,000	1-200,000,000
10 Gbit/s	2,000	200-20,000	1-200,000,000
100 Gbit/s	200	20-2,000	1-200,000,000
1 TBit/s	20	2-200	1-200,000,000
10 TBit/s	2	1-20	1-200,000,000

Table 4: Recommended path costs for RSTP based on the data rate.

a. Bridges that conform with IEEE 802.1D 1998 and only support 16-bit values for the path costs should use the value 65,535 (FFFFH) for path costs when they are used in conjunction with bridges that support 32-bit values for the path costs.

#### **6.1.5** Port Identifier

The port identifier consists of 2 bytes. One part, the lower-value byte, contains the physical port number. This provides a unique identifier for the port of this bridge. The second, higher-value part is the port priority, which is specified by the Administrator (default value: 128). It also applies here that the port with the smallest number for the port identifier has the highest priority.

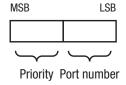

Figure 31: Port Identifier

## **6.1.6** Max Age and Diameter

The "Max Age" and "Diameter" values largely determine the maximum expansion of a Spanning Tree network.

#### Diameter

The number of connections between the devices in the network that are furthest removed from each other is known as the network diameter.

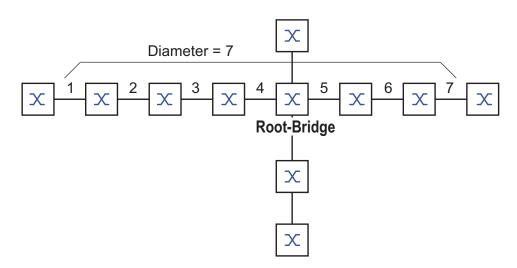

Figure 32: Definition of diameter

The network diameter that can be achieved in the network is MaxAge-1. In the state on delivery, MaxAge=20 and the maximum diameter that can be achieved=19. If you set the maximum value of 40 for MaxAge, the maximum diameter that can be achieved=39.

#### MaxAge

Every STP-BPDU contains a "MessageAge" counter. When a bridge is passed through, the counter increases by 1.

Before forwarding a STP-BPDU, the bridge compares the "MessageAge" counter with the "MaxAge" value defined in the device:

- ☐ If MessageAge < MaxAge, the bridge forwards the STP-BPDU to the next bridge.
- ☐ If MessageAge = MaxAge, the bridge discards the STP-BPDU.

#### **Root-Bridge**

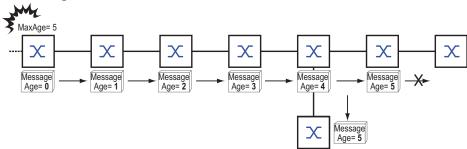

Figure 33: Transmission of an STP-BPDU depending on MaxAge

# 6.2 Rules for Creating the Tree Structure

## **6.2.1 Bridge information**

To determine the tree structure, the bridges need more detailed information about the other bridges located in the network.

To obtain this information, each bridge sends a BPDU (Bridge Protocol Data Unit) to the other bridges.

The contents of a BPDU include

- bridge identifier,
- root path costs and
- port identifier

(see IEEE 802.1D).

## **6.2.2** Setting up the tree structure

- ► The bridge with the smallest number for the bridge identifier is called the root bridge. It is (or will become) the root of the tree structure.
- ➤ The structure of the tree depends on the root path costs. Spanning Tree selects the structure so that the path costs between each individual bridge and the root bridge become as small as possible.

- ▶ If there are multiple paths with the same root path costs, the bridge further away from the root decides which port it blocks. For this purpose, it uses the bridge identifiers of the bridge closer to the root. The bridge blocks the port that leads to the bridge with the numerically higher ID (a numerically higher ID is the logically worse one). If 2 bridges have the same priority, the bridge with the numerically larger MAC address has the numerically higher ID, which is logically the worse one.
- ▶ If multiple paths with the same root path costs lead from one bridge to the same bridge, the bridge further away from the root uses the port identifier of the other bridge as the last criterion (see figure 31). In the process, the bridge blocks the port that leads to the port with the numerically higher ID (a numerically higher ID is the logically worse one). If 2 ports have the same priority, the port with the higher port number has the numerically higher ID, which is logically the worse one.

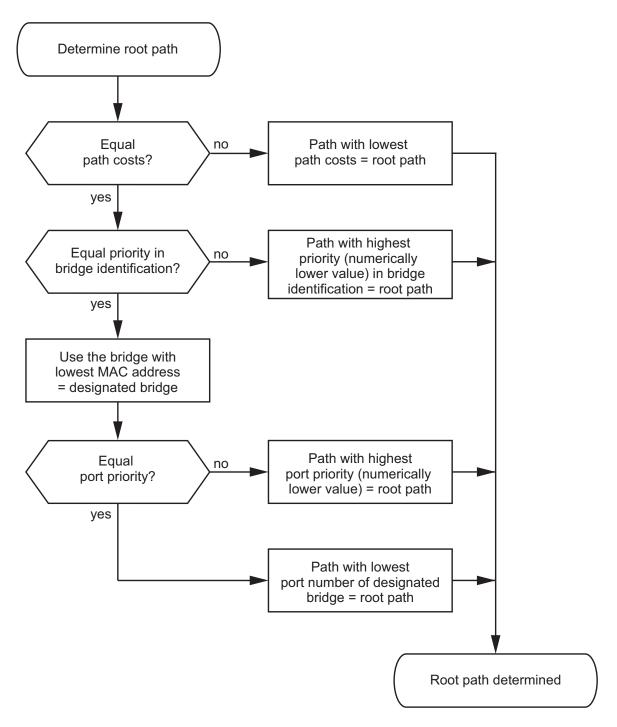

Figure 34: Flow diagram for specifying the root path

## 6.3 Examples

## 6.3.1 Example of determining the root path

You can use the network plan (see figure 35) to follow the flow chart (see figure 34) for determining the root path. The administrator has specified a priority in the bridge identification for each bridge. The bridge with the smallest numerical value for the bridge identification takes on the role of the root bridge, in this case, bridge 1. In the example all the sub-paths have the same path costs. The protocol blocks the path between bridge 2 and bridge 3 as a connection from bridge 3 via bridge 2 to the root bridge would result in higher path costs.

The path from bridge 6 to the root bridge is interesting:

- ► The path via bridge 5 and bridge 3 creates the same root path costs as the path via bridge 4 and bridge 2.
- ➤ STP selects the path using the bridge that has the lowest MAC address in the bridge identification (bridge 4 in the illustration).
- ► There are also 2 paths between bridge 6 and bridge 4. The port identifier is decisive here (Port 1 < Port 3).

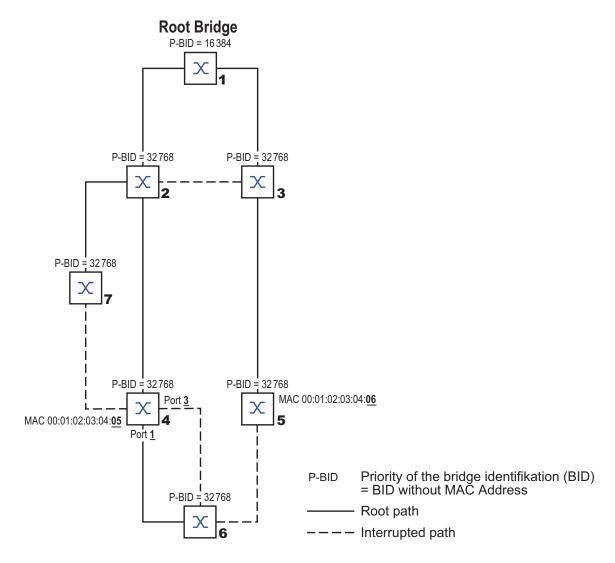

Figure 35: Example of determining the root path

**Note:** Because the Administrator does not change the default values for the priorities of the bridges in the bridge identifier, apart from the value for the root bridge, the MAC address in the bridge identifier alone determines which bridge becomes the new root bridge if the current root bridge goes down.

## 6.3.2 Example of manipulating the root path

You can use the network plan (see figure 36) to follow the flow chart (see figure 34) for determining the root path. The Administrator has performed the following:

- Left the default value of 32,768 (8000H) for every bridge apart from bridge 1 and bridge 5, and
- assigned to bridge 1 the value 16,384 (4000H), thus making it the root bridge.
- To bridge 5 he assigned the value 28,672 (7000H).

The protocol blocks the path between bridge 2 and bridge 3 as a connection from bridge 3 via bridge 2 to the root bridge would mean higher path costs.

The path from bridge 6 to the root bridge is interesting:

The bridges select the path via bridge 5 because the value 28,672 for the priority in the bridge identifier is smaller than value 32,768.

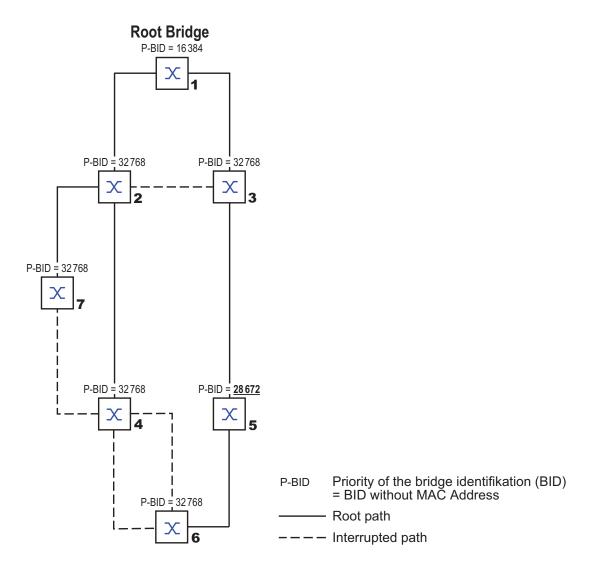

Figure 36: Example of manipulating the root path

## 6.3.3 Example of manipulating the tree structure

The Management Administrator soon discovers that this configuration with bridge 1 as the root bridge (see on page 80 "Example of determining the root path") is invalid. On the paths from bridge 1 to bridge 2 and bridge 1 to bridge 3, the control packets which the root bridge sends to all other bridges add up. If the Management Administrator configures bridge 2 as the root bridge, the burden of the control packets on the subnetworks is distributed much more evenly. The result is the configuration shown here (see figure 37). The path costs for most of the bridges to the root bridge have decreased.

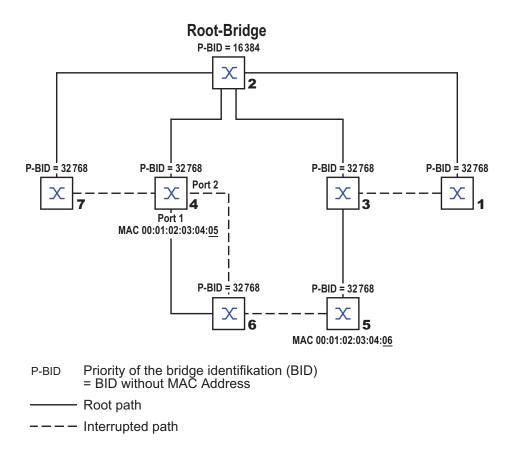

Figure 37: Example of manipulating the tree structure

## 6.4 The Rapid Spanning Tree Protocol

The RSTP uses the same algorithm for determining the tree structure as STP. RSTP merely changes parameters, and adds new parameters and mechanisms that speed up the reconfiguration if a link or bridge becomes inoperable.

The ports play a significant role in this context.

#### 6.4.1 Port roles

RSTP assigns each bridge port one of the following roles (see figure 38):

#### Root Port:

This is the port at which a bridge receives data packets with the lowest path costs from the root bridge.

If there are multiple ports with equally low path costs, the bridge ID of the bridge that leads to the root (designated bridge) decides which of its ports is given the role of the root port by the bridge further away from the root. If a bridge has multiple ports with equally low path costs to the same bridge, the bridge uses the port ID of the bridge leading to the root (designated bridge) to decide which port it selects locally as the root port (see figure 34).

The root bridge itself does not have a root port.

## Designated port:

The bridge in a network segment that has the lowest root path costs is the designated bridge.

If more than 1 bridge has the same root path costs, the bridge with the smallest value bridge identifier becomes the designated bridge. The designated port on this bridge is the port that connects a network segment leading away from the root bridge. If a bridge is connected to a network segment with more than one port (via a hub, for example), the bridge gives the role of the designated port to the port with the better port ID.

#### Edge port

Every network segment with no additional RSTP bridges is connected with exactly one designated port. In this case, this designated port is also an edge port. The distinction of an edge port is the fact that it does not receive any RST BPDUs (Rapid Spanning Tree Bridge Protocol Data Units).

#### Alternate port

This is a blocked port that takes over the task of the root port if the connection to the root bridge is lost. The alternate port provides a backup connection to the root bridge.

Backup port

This is a blocked port that serves as a backup in case the connection to the designated port of this network segment (without any RSTP bridges) is lost

Disabled port

This is a port that does not participate in the Spanning Tree Operation, i.e., the port is switched off or does not have any connection.

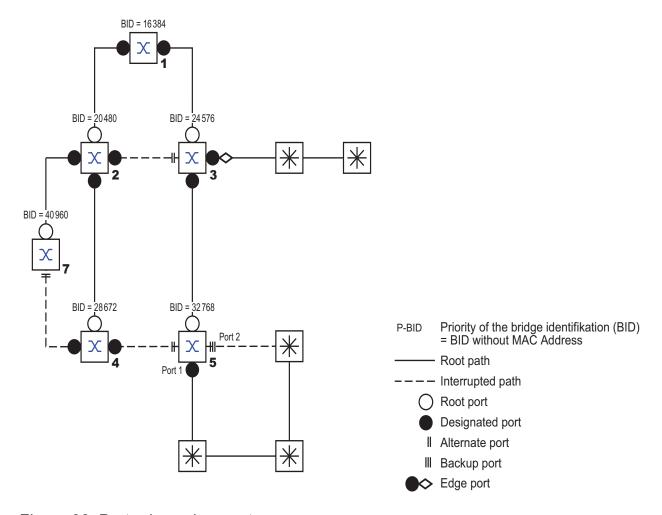

Figure 38: Port role assignment

#### 6.4.2 Port states

Depending on the tree structure and the state of the selected connection paths, the RSTP assigns the ports their states.

STP port state	Administrative bridge port state	MAC operational	RSTP Port state	Active topology (port role)
DISABLED	Disabled	FALSE	Discarding <sup>a</sup>	Excluded (disabled)
DISABLED	Enabled	FALSE	Discarding <sup>a</sup>	Excluded (disabled)
BLOCKING	Enabled	TRUE	Discarding <sup>b</sup>	Excluded (alternate, backup)
LISTENING	Enabled	TRUE	Discarding <sup>b</sup>	Included (root, designated)
LEARNING	Enabled	TRUE	Learning	Included (root, designated)
FORWARDING	Enabled	TRUE	Forwarding	Included (root, designated)

Table 5: Relationship between port state values for STP and RSTP.

## Meaning of the RSTP port states:

- Disabled: Port does not belong to the active topology
- Discarding: No address learning in FDB, no data traffic except for STP BPDUs
- Learning: Address learning active (FDB) and no data traffic except for STP BPDUs
- ► Forwarding: Address learning is active (FDB), sending and receipt of all frame types (not only STP BPDUs)

a. The dot1d-MIB displays "Disabled"b. The dot1d-MIB displays "Blocked"

## **6.4.3 Spanning Tree Priority Vector**

To assign roles to the ports, the RSTP bridges exchange configuration information with each other. This information is known as the Spanning Tree Priority Vector. It is part of the RSTP BPDUs and contains the following information:

- Bridge identification of the root bridge
- Root path costs of the sending bridge
- Bridge identification of the sending bridge
- ▶ Port identifiers of the ports through which the message was sent
- Port identifiers of the ports through which the message was received

Based on this information, the bridges participating in RSTP are able to determine port roles themselves and define the port states of their own ports.

## 6.4.4 Fast reconfiguration

Why can RSTP react faster than STP to an interruption of the root path?

- Introduction of edge-ports:
  - During a reconfiguration, RSTP switches an edge port into the transmission mode after three seconds (default setting) and then waits for the "Hello Time" to elapse, to be sure that no bridge sending BPDUs is connected.
  - When the user ensures that a terminal device is connected at this port and will remain connected, there are no waiting times at this port in the case of a reconfiguration.
- Introduction of alternate ports: As the port roles are already distributed in normal operation, a bridge can immediately switch from the root port to the alternate port after the connection to the root bridge is lost.
- Communication with neighboring bridges (point-to-point connections): Decentralized, direct communication between neighboring bridges enables reaction without wait periods to status changes in the spanning tree topology.

- Address table:
  - With STP, the age of the entries in the FDB determines the updating of communication. RSTP immediately deletes the entries in those ports affected by a reconfiguration.
- Reaction to events: Without having to adhere to any time specifications, RSTP immediately reacts to events such as connection interruptions, connection reinstatements, etc.

**Note:** The downside of this fast reconfiguration is the possibility that data packages could be duplicated and/or arrive at the recipient in the wrong order during the reconfiguration phase of the RSTP topology. If this is unacceptable for your application, use the slower Spanning Tree Protocol or select one of the other, faster redundancy procedures described in this manual.

## 6.4.5 STP compatibility mode

The STP compatibility mode allows you to operate RSTP devices in networks with old installations. If an RSTP device detects an older STP device, it switches on the STP compatibility mode at the relevant port.

## 6.5 Configuring the device

RSTP configures the network topology completely independently. The device with the lowest bridge priority automatically becomes the root bridge. However, to define a specific network structure regardless, you specify a device as the root bridge. In general, a device in the backbone takes on this role.

Set up the network to meet your requirements, initially without redundant lines.
You deactivate the flow control on the participating ports. If the flow control and the redundancy function are active at the same time, there is a risk that the redundancy function will not operate as intended. (Default setting: flow control deactivated globally and activated on all ports.)
Switch MRP off on all devices.
Switch Spanning Tree on on all devices in the network. In the state on delivery, Spanning Tree is switched on on the device.

- ☐ Open the Switching > L2-Redundancy > Spanning Tree > Global dialog.
- ☐ Activate the function.

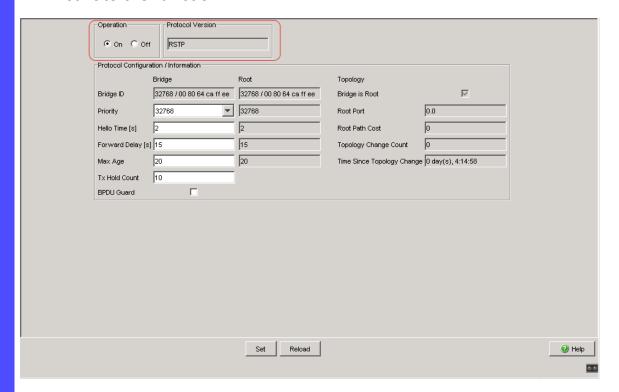

Figure 39: Switching the function on

 $\square$  Click "Set" to save the changes.

enable
configure
spanning-tree operation
show spanning-tree global

Switch to the privileged EXEC mode. Switch to the Configuration mode. Switches Spanning Tree on. Displays the parameters for checking.

- ☐ Now connect the redundant lines.
- ☐ Define the settings for the device that takes over the role of the root bridge.
  - ☐ In the "Priority"field you enter a numerically lower value.

    The bridge with the numerically lowest bridge ID has the highest priority and becomes the root bridge of the network.

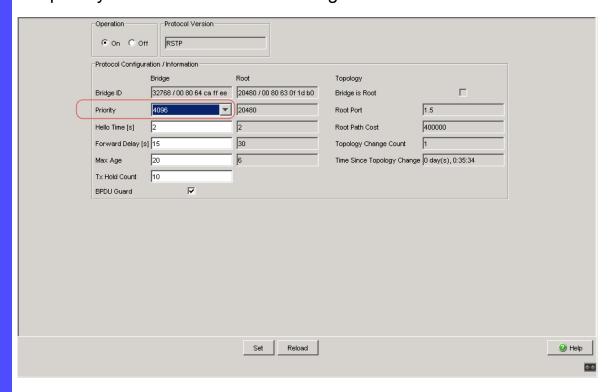

Figure 40: Defining the bridge priority

 $\square$  Click "Set" to save the changes.

```
spanning-tree mst priority 0 Defines the bridge priority of the device.
<0..61440
in 4096er-Schritten>
```

After saving, the dialog shows the following information:

- The "Bridge is Root" checkbox is marked.
- The "Root Port" field shows the value 0.0.
- The "Root Path Cost" field shows the value 0.

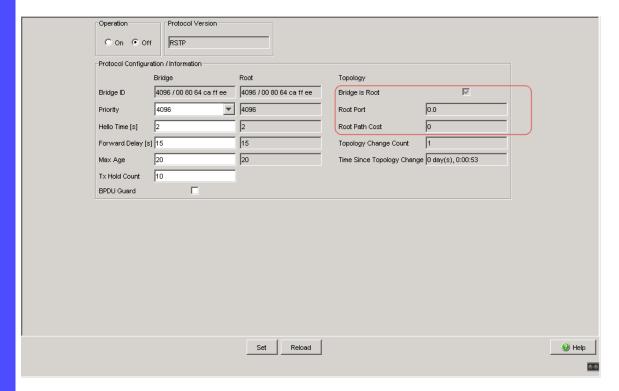

Figure 41: Device is operating as root bridge

show spanning-tree global Displays the parameters for checking.

- ☐ If applicable, change the values in the "Forward Delay [s]" and "Max Age" fields.
  - The root bridge transmits the changed values to the other devices.

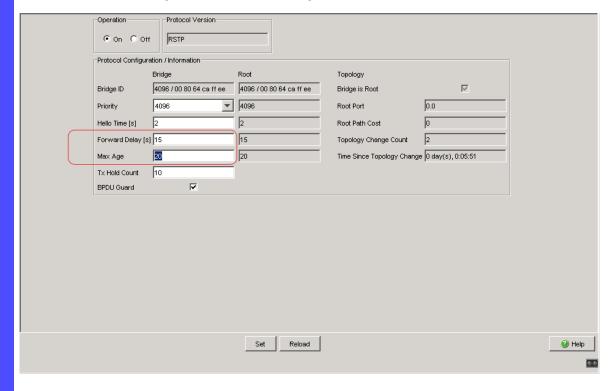

Figure 42: Changing Forward Delay and Max Age

☐ Click "Set" to save the changes.

```
spanning-tree forward-time <4..30>
spanning-tree max-age seconds.

spanning-tree max-age Specifies the delay time for the status change in seconds.

Specifies the maximum permissible branch length, i.e. the number of devices to the root bridge.

show spanning-tree global Displays the parameters for checking.
```

**Note:** The parameters "Forward Delay [s]" and "Max Age" have the following relationship:

"Forward Delay [s]" ≥ ("Max Age"/2) + 1

If you enter values in the fields that contradict this relationship, the device replaces these values with the last valid values or with the default value.

Note: If possible, do not change the value in the "Hello Time" field.

- ☐ Check the following values in the other devices:
  - Bridge ID (bridge priority and MAC address) of the corresponding device and the root bridge.
  - Number of the device port that leads to the root bridge.
  - Path cost from the root port of the device to the root bridge.

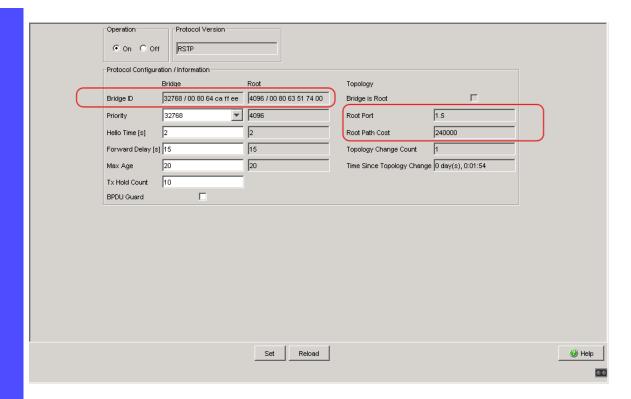

Figure 43: Check values

show spanning-tree global

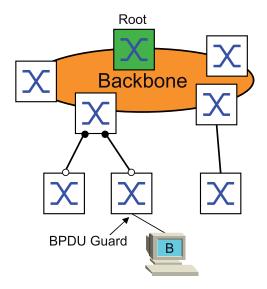

Displays the parameters for checking.

## 6.6 Guards

The device allows you to activate various protection functions (guards) on the device ports.

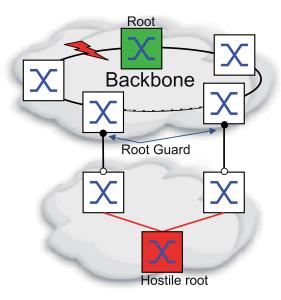

The following protection functions help protect your network from incorrect configurations, loops and attacks with STP-BPDUs:

▶ BPDU Guard – for manually defined terminal device ports (edge ports) You activate this protection function globally in the device.

Terminal device ports do not normally receive any STP-BPDUs. If an attacker still attempts to feed in STP-BPDUs at this port, the device deactivates the device port.

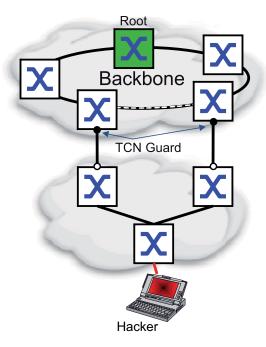

▶ Root Guard – for designated ports You activate this protection function separately for every device port.

If a designated port receives an STP-BPDU with better path information to the root bridge, the device discards the STP-BPDU and sets the transmission state of the port to discarding instead of root. If there are no STP-BPDUs with better path information to the root bridge, after 2 x Hello Time the device resets the state of the port to a value according to the port role.

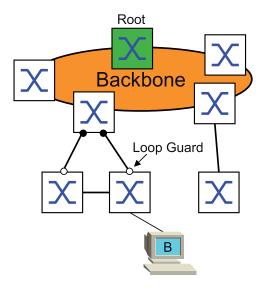

► TCN Guard – for ports that receive STP-BPDUs with a Topology Change flag

You activate this protection function separately for every device port.

If the protection function is activated, the device ignores Topology Change flags in received STP-BPDUs. This does not change the content of the address table (FDB) of the device port. However, additional information in the BPDU that changes the topology is processed by the device.

Loop Guard – for root, alternate and backup ports You activate this protection function separately for every device port.

This protection function prevents the transmission status of a port from unintentionally being changed to forwarding if the port does not receive any more STP-BPDUs. If this situation occurs, the device designates the loop status of the port as inconsistent, but does not forward any data packets.

## 6.6.1 Activating the BPDU Guard

☐ Open the Switching > L2-Redundancy > Spanning Tree > Global dialog.

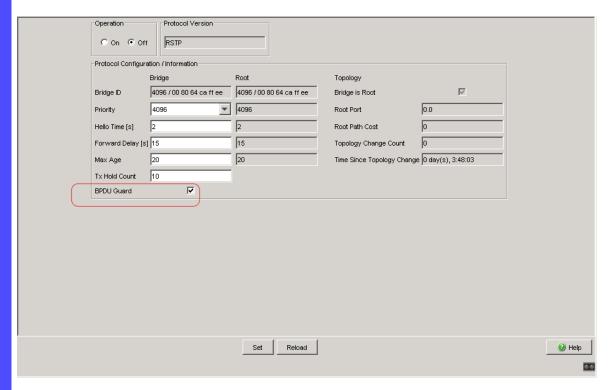

Figure 44: Activating the BPDU Guard

 $\ \square$  Click "Set" to save the changes.

enable
configure
spanning-tree bpdu-guard
show spanning-tree global

Switch to the privileged EXEC mode. Switch to the Configuration mode. Activates the BPDU Guard. Displays the parameters for checking.

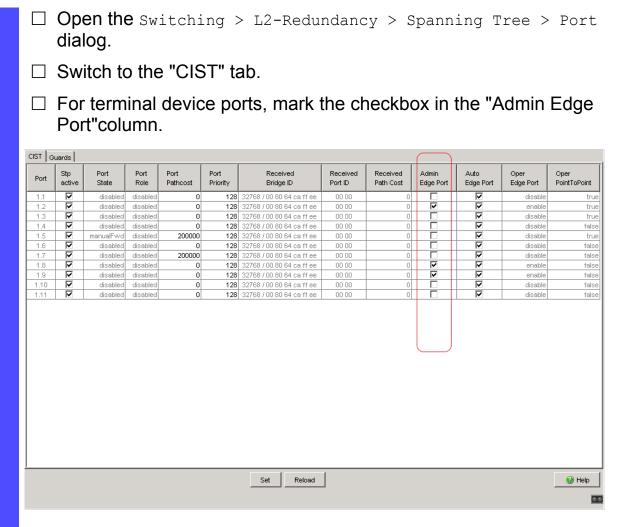

Figure 45: Switching > L2-Redundancy > Spanning Tree > Port dialog, "CIST" tab

☐ Click "Set" to save the changes.

interface x/y
spanning-tree edge-port

show spanning-tree port x/y
exit

Switches to the interface mode.

Designates the port as a terminal device port (edge port).

Displays the parameters for checking. Leaves the interface mode. If an edge port receives an STP-BPDU, the device behaves as follows:

► The device deactivates this port.

In the Basic Settings > Port dialog, "Configuration" tab, the checkbox in the "Port on" column is not marked for this port.

The device designates the port.

In the Switching > L2-Redundancy > Spanning Tree > Port dialog, "Guards" tab, the device shows the value enable in the "BPDU Guard Effect" column.

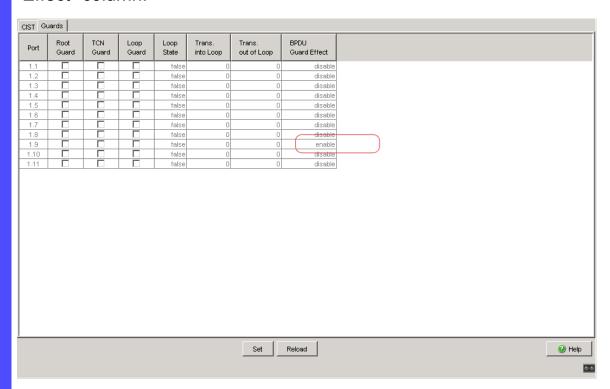

Figure 46: Switching > L2-Redundancy > Spanning Tree > Port dialog, "Guards" tab

show spanning-tree port x/y

Displays the parameters of the port for checking. The value of the "BPDU Guard Effect" parameter is enable.

reset the status of the device port to the value forwarding, you proceed follows:
If the device port is still receiving BPDUs:
<ul> <li>Remove the manual definition as an edge port.</li> </ul>
or
<ul> <li>Deactivate the BPDU Guard</li> </ul>
Activate the device port again.

## 6.6.2 Activating Root Guard / TCN Guard / Loop Guard

☐ Open the Switching > L2-Redundancy > Spanning Tree > Port dialog. ☐ Switch to the "Guards" tab. ☐ For designated ports, select the checkbox in the "Root Guard" column. ☐ For ports that receive STP-BPDUs with a Topology Change flag. select the checkbox in the "TCN Guard" column. ☐ For root, alternate or backup ports, mark the checkbox in the "Loop" Guard" column. CIST Guards TCN Loop Guard Trans BPDU disable disable false Set Reload Help

Figure 47: Activating Guards

**Note:** The "Root Guard" and "Loop Guard" functions are mutually exclusive. If you switch on the "Root Guard" function while the "Loop Guard" function is switched on, the device switches off the "Loop Guard" function.

☐ Click "Set" to save the changes.

show spanning-tree port x/y

Switch to the privileged EXEC mode. enable Switch to the Configuration mode. configure Switches to the interface mode. interface x/y Switches the Root Guard on at the designated spanning-tree guard-root port. Switches on the TCN Guard on the port that spanning-tree guard-tcn receives STP-BPDUs with a Topology Change flag. Switches the Loop Guard on at a root, alternate or spanning-tree guard-loop backup port. Leaves the interface mode. exit

Displays the parameters of the port for checking.

## 7 Link Aggregation

Link Aggregation using the single switch method helps you overcome 2 limitations with ethernet links, namely bandwidth, and redundancy.

The first problem that the Link Aggregation Group (LAG) function helps you with is bandwidth limitations of individual ports. LAG allows you to combine 2 or more links in parallel, creating 1 logical link between 2 devices. The parallel links increase the bandwidth for traffic between the 2 devices.

You typically use Link Aggregation on the network backbone. The function provides you an inexpensive way to incrementally increase bandwidth.

Furthermore, Link Aggregation provides for redundancy with a seemless failover. With 2 or more links configured in parallel, when a link goes down, the other links in the group continue to forward traffic.

The device uses a hash option to determine load balancing across the port group. Tagging the egress traffic allows the device to transmit associated packets across the same link.

The default settings for a new Link Aggregation instance are as follows:

- ▶ "Hashing Option" in the "Configuration" frame is sourceDestMacVlan
- "Active" is marked
- "Link Trap" is enabled
- "Static Link Aggregation" is disabled
- ▶ "Hashing Option" for new trunks is sourceDestMacVlan
- "Min. Active Ports" is 1

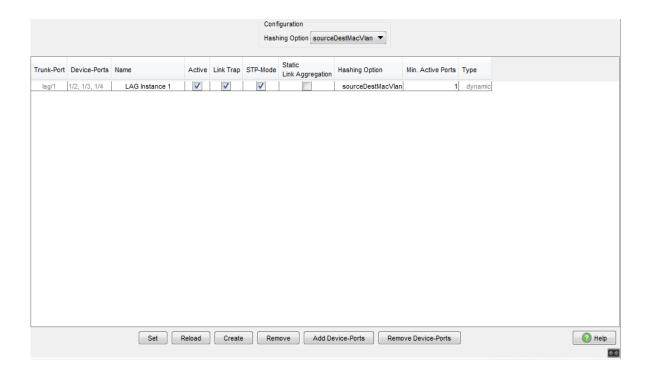

Figure 48: Switching > L2-Redundancy > Link Aggregation

# 7.1 Methods of Operation

The device operates on the Single Switch method. The Single Switch method provides you an inexpensive way to grow your network. The single switch method states that you need 1 device on each side of a link to provide the physical ports. The device balances the traffic load across the group member ports.

The device also uses the Same Link Speed method in which the group member ports are full-duplex, point-to-point links having the same transmission rate. The first port the user adds to the group is the master port and determines the bandwidth for the other member ports of the Link Aggregation Group.

The device allows you to configure up to 4 Link Aggregation Groups with up to 4 ports in each group.

#### Hash Algorithm

The frame distributor is responsible for receiving frames from the end devices and transmitting them over the Link Aggregation Group. The frame distributor implements a distribution algorithm responsible for choosing the link used for transmitting any given frame or set of frames. The hash option helps you achieve load balancing across the group.

The following list contains options which you set for link selection.

- Source MAC address, VLAN ID, EtherType, and receiving port
- ▶ Destination MAC address, VLAN ID, EtherType, and receiving port
- Source/Destination MAC address, VLAN ID, EtherType, and receiving port
- Source IP address and Source TCP/UDP port
- ▶ Destination IP address and destination TCP/UDP port
- Source/destination IP address and source/destination TCP/UDP port

#### ■ Static and Dynamic Links

The device allows you to set up static and dynamic links.

- ▶ Static Links The administrator sets up and maintains the links manually. For example, when a link fails and there is a media converter between the devices, the media converter continues forwarding traffic on the link causing the link to fail. Another possibility is that cabling or an undetected configuration mistake causes undesirable network behavior. In this case, the network administrator manually changes the link setup to restore traffic.
- Dynamic Links The device confirms that the setup on the remote device is able to handle link aggregation and failover occurs automatically.

# 7.2 Link Aggregation Example

Connect multiple workstations using one aggregated link group between switch 1 and 2. By aggregating multiple links, higher speeds are achievable without a hardware upgrade.

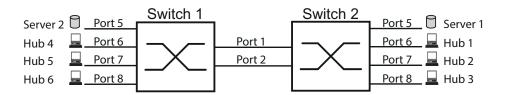

Figure 49: Link Aggregation Switch to Switch Network

Use the following worksteps to setup switch 1 and 2 in the graphical user interface.

enable
configure
link-aggregation add lag/1
link-aggregation modify
lag/1 addport 1/1
link-aggregation modify
lag/1 addport 1/2

Switch to the privileged EXEC mode. Switch to the Configuration mode. Create a Link-Aggregation group lag/1 Adds port 1/1 to the Link Aggregation Group.

Adds port 1/2 to the Link Aggregation Group.

# 8 MRP over LAG (HiOS-2A, HiOS-3S)

Hirschmann devices allow you to combine Link Aggregation Groups (LAG) to increase bandwidth with the Media Redundancy Protocol (MRP) providing redundancy. The function allows you to increase the bandwidth on individual segments or on the entire network.

The LAG function helps you overcome bandwidth limitations of individual ports. LAG allows you to combine 2 or more links in parallel, creating 1 logical link between 2 devices. The parallel links increase the bandwidth for the data stream between the 2 devices. For a detailed description of the LAG function, see "Link Aggregation" on page 107.

An MRP ring consists of up to 50 devices that support the MRP protocol according to IEC 62439. If you use only Hirschmann devices, then the protocol allows you to configure MRP rings with up to 100 devices. For a detailed description of the MRP protocol, see "Media Redundancy Protocol (MRP)" on page 17.

You use MRP over LAG in the following cases:

- ▶ to increase bandwidth only on specific segments of an MRP ring
- to increase bandwidth on the entire MRP ring

#### **8.1 Network Structure**

When configuring an MRP ring with LAGs, the Ring Manager (RM) monitors both ends of the backbone for continuity. The RM blocks data on the secondary (redundant) port as long as the backbone is intact. If the RM detects an interruption of the data stream on the ring, then it begins forwarding data on the secondary port, which restores backbone continuity.

You use LAG instances in MRP rings to increase bandwidth only, in this case MRP provides the redundancy.

In order for the RM to detect an interruption on the ring, MRP requires a device to block every port in the LAG instance when a port in the instance is down.

#### 8.1.1 LAG on a single segment of an MRP ring

The device allows you to configure a LAG instance on specific segments of an MRP ring.

You use the LAG Single Switch method for devices in the MRP ring. The Single Switch method provides you an inexpensive way to grow your network by using only 1 device on each side of a segment to provide the physical ports. You group the ports of the device into a LAG instance to provide increased bandwidth on specific segments where needed.

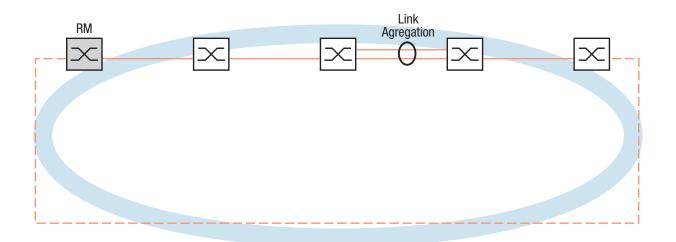

Figure 50: Link Aggregation over a single link of an MRP ring.

#### 8.1.2 LAG on an entire MRP ring

Besides being able to configure a LAG instance on specific segments of an MRP ring, Hirschmann devices also allow you to configure LAG instances on every segment, which increases bandwidth on the entire MRP ring.

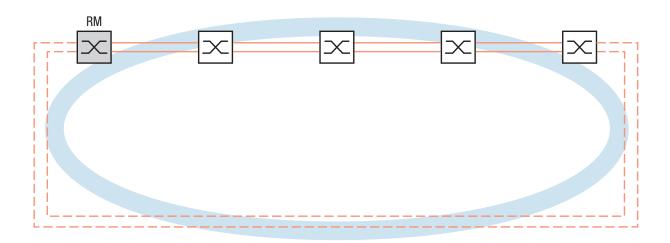

Figure 51: Link Aggregation over the entire MRP ring.

#### 8.1.3 Detecting interruptions on the ring

When configuring the LAG instance, specify the "Min. Active Ports" value to equal the total number of ports used in the LAG instance. If a device detects an interruption on a port in the LAG instance, then it blocks data on the other ports of the instance. With every port of an instance blocked, the RM senses that the ring is open and begins forwarding data on the secondary port. This way the RM is able to restore continuity to the devices on the other side of the interrupted segment.

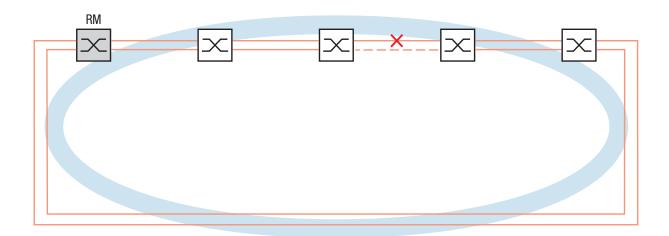

Figure 52: Interruption of a link in an MRP ring.

# 8.2 Example Configuration

In the following example, switch A and switch B link to departments together. The departments produce traffic too large for the individual port bandwidth to handle. You configure a LAG instance for the single segment of the MRP ring, increasing the bandwidth of the segment.

The prerequisite for the example configuration is that you begin with an operational MRP ring. For details on how to configure an MRP ring see "Media Redundancy Protocol (MRP)" on page 17.

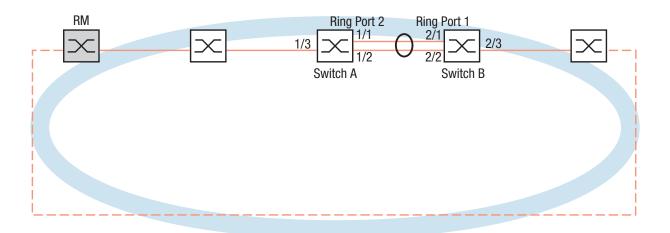

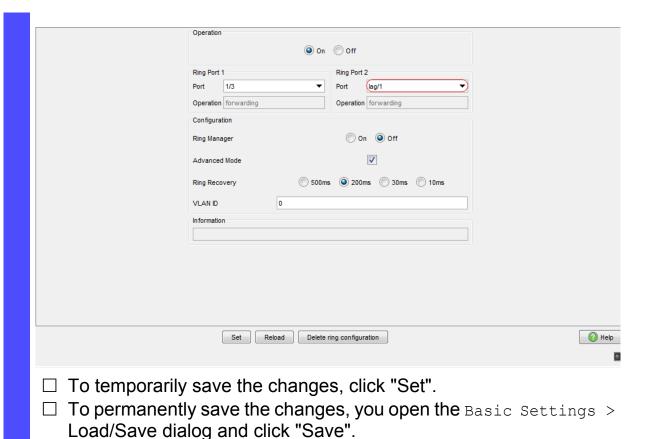

Figure 53: MRP over LAG Configuration Example

Using the following worksteps configure switch A. Configure switch B using the same worksteps, substituting the appropriate port and ring port numbers.

$\square$ Open the Switching > L2-Redundancy > Link Aggregation dialog
$\square$ To make a new entry in the table, click "Create".
In the "Create" dialog, the device automatically enters the number of the next available instance in the "Lag Index" field. The device also allows you to select another number for the instance from the pull
down menu.
☐ Click "OK".

enable
configure
link-aggregation add lag/1
link-aggregation modify
lag/1 addport 1/1
link-aggregation modify
lag/1 addport 1/2
mrp domain modify port
secondary lag/1
copy config running-config
nvm

Switch to the privileged EXEC mode.
Switch to the Configuration mode.
Create a Link-Aggregation group lag/1
Adds port 1/1 to the Link Aggregation Group.

Adds port 1/2 to the Link Aggregation Group.

Defines port lag/1 as ring port 2 (secondary).

The device stores the current configuration data in the local non-volatile memory.

# 9 Link Backup

Link Backup provides a redundant link for traffic on Layer 2 devices. When the device detects an error on the primary link, then the device transfers traffic to the backup link. You typically use Link Backup in service-provider or enterprise networks.

You set up the backup links in pairs, one as a primary and one as a backup. When providing redundancy for enterprise networks for example, the device allows you to set up more than 1 pair. The maximum number of link backup pairs is: total number of physical ports / 2. Furthermore, the device sends an SNMP trap when the state of a port participating in a link backup pair changes.

When configuring link backup pairs remember the following rules:

- ▶ A link pair consists of any combination of physical ports. For example, when 1 port is a 100 Mbit port and the other is a 1000 Mbit SFP port.
- ▶ A specific port is a member of 1 link backup pair at any given time.
- Verify that the ports of a link backup pair are members of the same VLAN with the same VLAN ID. When the primary port or backup port is a member of a VLAN then, assign the second port of the pair to the same VLAN.

The default setting for this function is inactive without any link backup pairs.

**Note:** Verify that the Spanning Tree Protocol is disabled on the Link Backup ports.

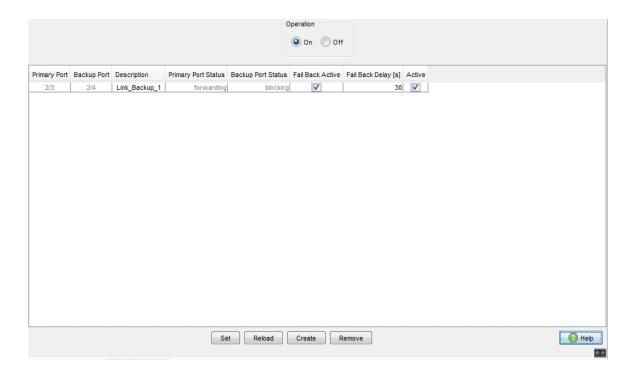

Figure 54: "Link Backup" dialog

# 9.1 Fail Back Description

Link Backup also allows you to set up a Fail Back option. When you activate the fail back function and the primary link returns to normal operation, the device first blocks traffic on the backup port and then forwards traffic on the primary port. This process helps protect the device from causing loops in the network.

When the primary port returns to the link up and active state, the device supports 2 modes of operation:

- ▶ When you inactivate "Fail Back Active", the primary port remains in the blocking state until the backup link fails.
- ▶ When you activate "Fail Back Active", and after the "Fail Back Delay [s]" timer expires, the primary port returns to the forwarding state and the backup port changes to down.

In the cases listed above, the port forcing its link to forward traffic, first sends a "flush FDB" packet to the remote device. The flush packet helps the remote device guickly relearn the MAC addresses.

# 9.2 Example Configuration

In the example network below, you connect ports 2/3 and 2/4 on switch A to the uplink switches B and C. When you set up the ports as a Link Backup pair, 1 of the ports forwards traffic and the other port is in the blocking mode.

The primary, port 2/3 on switch A, is the active port and is forwarding traffic to port 1 on switch B. Port 2/4 on switch A is the backup port and is blocking traffic.

When switch A disables port 2/3 because of a detected error, then port 2/4 on switch A starts forwarding traffic to port 2 on switch C.

When port 2/3 returns to the active state, "no shutdown", with "Fail Back Active" activated, and "Fail Back Delay [s]" set to 30 s. After the timer expires, port 2/4 first blocks the traffic and then port 2/3 starts forwarding the traffic.

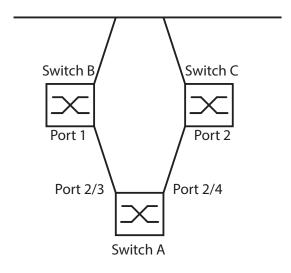

Figure 55: "Link Backup" example network

The following tables contain examples of parameters for Switch A set up.

☐ Open the Switching > L2-Redundancy > Link Backup dialog.
☐ To enter a new Link Backup pair in the table, click "Create".

☐ In the "Create" window, from the "Primary Port" drop-down menu
select 2/3 and from the "Backup Port" drop-down menu select 2/4
□ Click "OK".
☐ In the "Description" textbox, enter Link_Backup_1 as the name for the backup pair.
<ul> <li>To activate the Fail Back function for the link backup pair, mark the "Fail Back Active" checkbox.</li> </ul>
☐ Set the fail back timer for the link backup pair, enter 30 s in "Fail Back Delay [s]".
☐ To activate the the link backup pair, mark the "Active" checkbox.
<ul> <li>To enable the Link Backup function globally, in the "Operation" frame, mark the "On" radio button.</li> </ul>

enable
configure
interface 2/3
link-backup add 2/4

link-backup modify 2/4
description Link\_Backup\_1
link-backup modify 2/4 failback-status enable
link-backup modify 2/4 failback-time 30
link-backup modify 2/4 status
enable
exit
link-backup operation

Switch to the privileged EXEC mode.

Switch to the Configuration mode.

Switch to the Interface 2/3 Configuration mode.

Creates a Link Backup instance where port 2/3 is the primary port and port 2/4 is the backup port.

Defines Link\_Backup\_1 as the name of the backup pair.

Enables the fail back timer.

Defines the fail back delay time as 30 s.

Switch to the Configuration mode. Enables the Link Backup function globally on the device.

Enables the Link Backup instance.

### **A Readers' Comments**

What is your opinion of this manual? We are always striving to provide as comprehensive a description of our product as possible, as well as important information that will ensure trouble-free operation. Your comments and suggestions help us to further improve the quality of our documentation.

#### ■ Hirschmann Competence Center

The Hirschmann Competence Center is ahead of its competitors:

- Consulting incorporates comprehensive technical advice, from system evaluation through network planning to project planning.
- ► Training offers you an introduction to the basics, product briefing and user training with certification.
  - The current technology and product training courses can be found at <a href="http://www.hicomcenter.com">http://www.hicomcenter.com</a>
- Support ranges from the first installation through the standby service to maintenance concepts.

With the Hirschmann Competence Center, you have decided against making any compromises. Our client-customized package leaves you free to choose the service components you want to use. Internet:
